Mission sets considered in the capabilities assessment include: cargo; utility; armed scout; attack; humanitarian assistance; medical evacuation; anti-submarine warfare; anti-surface warfare; land/sea search and rescue; special warfare support; vertical replenishment; airborne mine countermeasures; and others.

As is shown in Figure D-7, three sizes of aircraft are anticipated with one set of missions and potential Service customers for the light vehicle, three for the medium vehicle and one for the heavy vehicle. Additional details are competition sensitive.

994 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The FVL family of aircraft will be required to have either optionally piloted or autonomous flight capabilities.

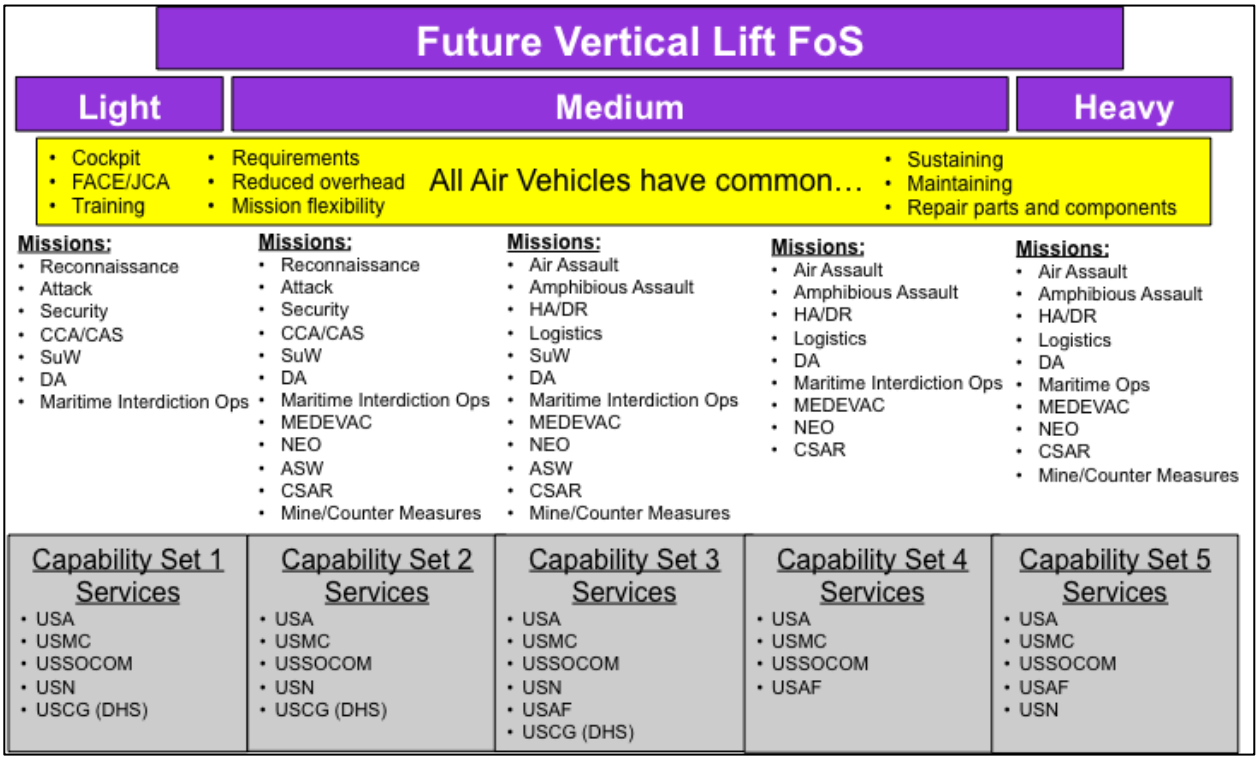

Figure D-7 The Future Vertical Lift Family

D.3 Findings Regarding JMR-TD and FVL FoS

The study team had several key findings with regard to JMR-TD and FVL FoS:

1. JMR-TD and FVL provide focus for Army Aviation S&T for next generation rotorcraft systems and provide a solid basis for much needed capability improvements (Ref. FVL ICD); however, there is no funding for FVL in the POM.
2. The JMR-TD vehicles are close in size and aerodynamic performance capability to the FVL medium class system.
3. The current FVL schedule leads to an IOC of the first system in the mid 2030s. It should be beneficial to accelerate this timeline through an evolutionary acquisition approach if funding allows.
4. The JMR-TD, DARPA X planes, USN/USMC prototyping efforts, and industry investment support talent development and retention in rotorcraft government and industry teams.

Based on these findings, the team recommended that ASA(ALT) develop an evolutionary acquisition approach for FVL to allow for earliest possible fielding consistent with funding constraints, as informed by the results of system of systems operational effectiveness analyses recommended elsewhere in this report.

995 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

APPENDIX E ARMY AVIATION EFFORTS

The Aviation Development Directorate (ADD) is responsible for aviation S&T within the Aviation and Missile Research Development and Engineering Command (AMRDEC). Figure E-1 shows the organization of ADD. For the most part the Aviation Applied Technology Directorate (AATD) is located at Joint Base Langley-Eustis in Virginia, the Aeroflightdynamics Directorate (AFDD) is at NASA Ames Moffett Field in California, and the remainder of the organization is at headquarters at Redstone Arsenal in Alabama.

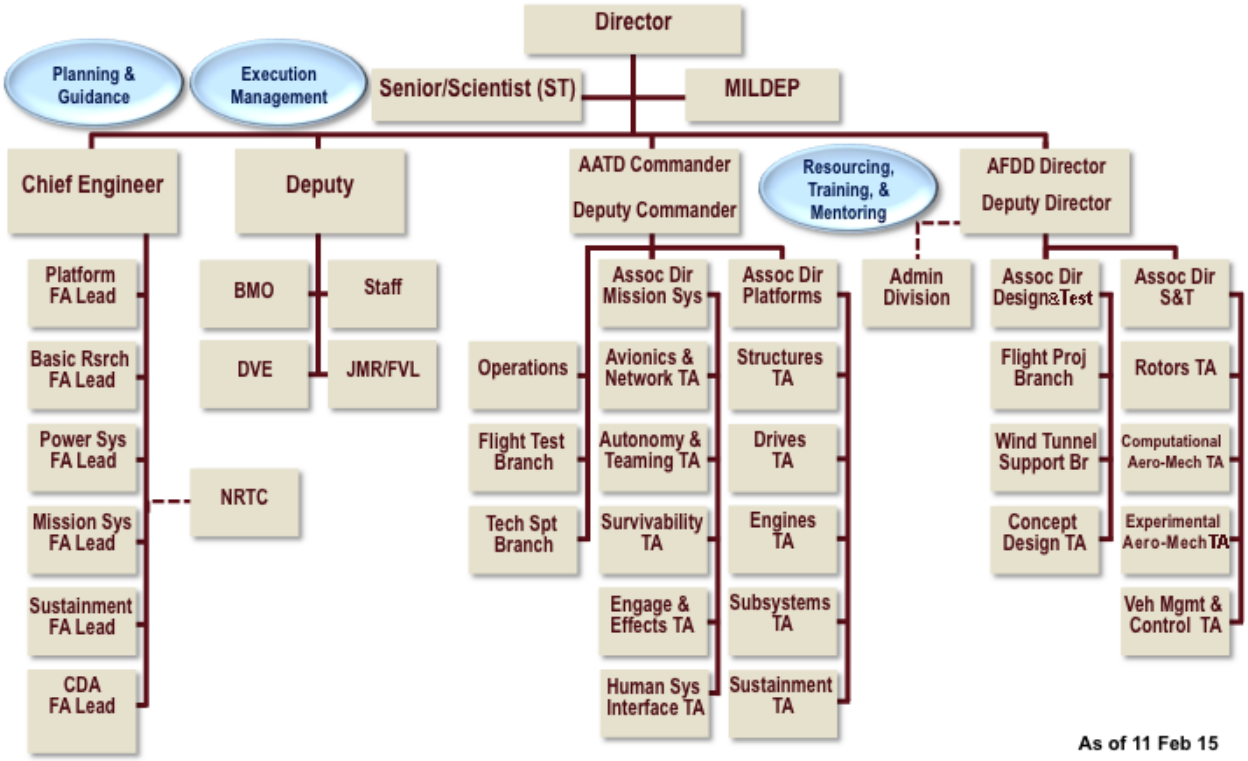

Figure E-1 Organization of the Aviation Development Directorate.

Figure E-2 shows the technology areas (TA) included in five of the ADD Focus Areas (FA). The sixth FA is Basic Research. Within these focus areas there are two major programs:

- Degraded Visual Environment Mitigation (DVE-M) in Mission Systems (see Section 3.1)
- Joint Multi-Role Technology Demonstrator (JMR-TD) in Platforms (see APPENDIX D)

996 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

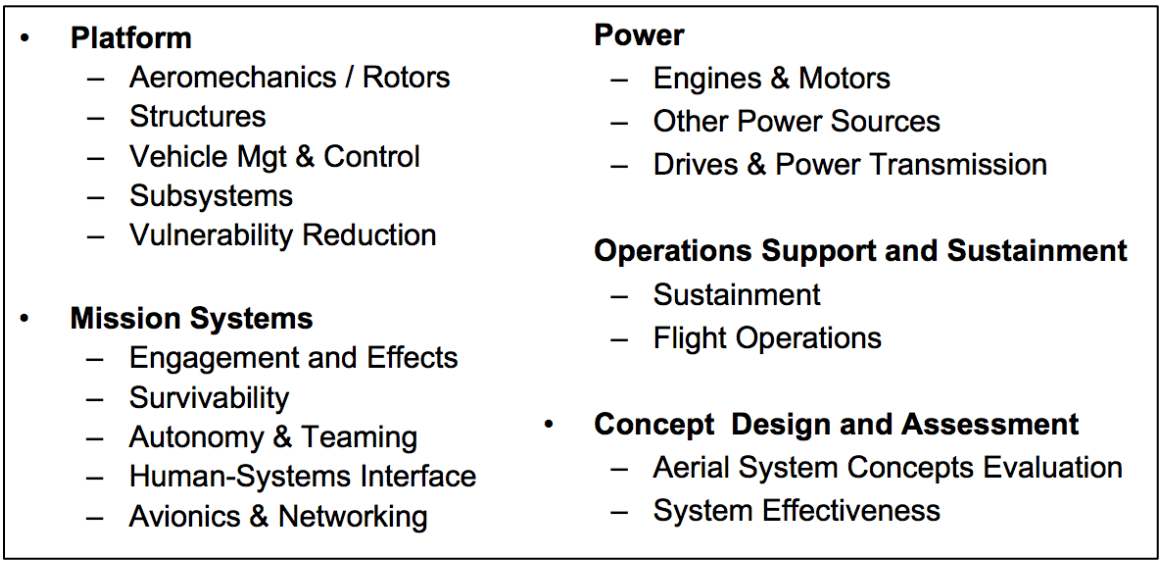

Figure E-2 ADD Focus Areas and Technology Areas

The Platform and Power Focus Areas were described in Section 3.5 in the Main Report. Mission Systems are described in Section 3.3 (manned-unmanned teaming) and Section 3.4 (lethality and survivability). The remaining focus areas are described below.

E.1 Operations Support and Sustainment

Programs in FY2016 Budget Documents

The Army's longstanding commitment to reducing maintenance costs and maximizing the performance and availability of aircraft, ground vehicles, and weapon systems is reflected in a wide range of RDT&E activities relevant to Condition-Based Maintenance (CBM) cited in the Fiscal Year 2016 Justification Book of Research, Development, Test & Evaluation, Army, Volumes 1-5.

For Budget Activity 1, Basic Research, specific efforts relevant to CBM involve research in the areas of advanced propulsion and structures. **Advanced Propulsion** efforts include work to develop thermal materials for advanced high-performance engines to reduce engine and transmission friction losses, improve performance, and reduce maintenance costs; on thermo-mechanical fatigue of materials; and on high-speed thermo-mechanical turbomachinery and mechanical energy transfer for future rotorcraft. It also includes development of advanced computational damage models and mechanical diagnostics experiments to improve the understanding of failure progression and diagnostics in drive train mechanical components, such as gears and bearings.

Advanced Structures basic research efforts include development of improved tools and methods to enable and enhance structural health monitoring capabilities and CBM for both rotorcraft and ground vehicles. It also includes work on composite structures able to meet the dynamic interaction requirements of future platforms identified by the Army Modernization Strategy. Overall, the research is intended to lead to safer and more affordable systems having

997 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

extended service life, reduced maintenance costs, enhanced durability, and reduced logistics footprints. The work involves structural integrity analyses and development of failure criteria and inspection methods that address fundamental technology deficiencies in both metallic and composite Army rotorcraft structures. It addresses an urgent need for improved structural analysis and validation methods to predict durability and damage tolerance of composite and metallic rotorcraft structures, and the need for advanced structural dynamics modeling methods for both rotating and fixed system components important to future aircraft reliability. Specific efforts are focused on advanced fatigue assessment methodologies for metallic structures, improved composites technology, developing damage progression models, assessing the practicality of damage-detection sensing modes, failure mechanisms, integrated stress-strength-inspection, and advanced methods for predicting rotor system vehicle vibratory loads and aircraft stability.

Applied Research (Budget Activity 2) relevant to Condition Based Maintenance for aircraft builds on advances being recorded in ongoing basic research efforts. **Platform Design & Structures Technologies** efforts include the development and application of modeling and simulation tools to design and perform analysis of the Family of Systems (FoS) for Future Vertical Lift (FVL) to support "Zero Maintenance" helicopter concepts; physics of failure modeling to improve reliability of system components and enable damage-tolerant component design; and investigation of methods for monitoring component loads. Planned work for FY 2016 will include the development of improved damage initiation and propagation models, application of modeling and simulation tools to support design of FVL/novel concepts, and investigation of high-strain capable, multifunctional structures that offer improvements in structural efficiency and enable ultra-reliable, operationally durable designs.

Applied research in the area of **Maintainability & Sustainability Technologies** seeks to develop prognostic and system health assessment technologies to enable an enhanced CBM supportability structure applicable to an ultra-reliable, low-maintenance approach to aircraft design that significantly reduces unscheduled maintenance, inspections, and operations and sustainment costs. This work includes development of embedded multifunctional sensors with built-in processing and communications, health assessment systems to support adaptive controls, technologies for component self-assessment, and usage tracking and embedded history. Plans for FY 2016 call for investigating wireless communication technologies, integrating health assessment technologies into the Joint Common Architecture (JCA)/avionics/cockpit, developing fly-by-wire with CBM monitoring capability, developing miniaturized wireless sensors with on-component processing, history and parts tracking, and investigating technologies for in-flight transmission of condition/performance data to ground.

Applied research in the **Rotor and Structure Technology** area is directed toward the development of improved tools and methodologies enabling more accurate design for improved component reliability and durability. Specific efforts involve prognostic and diagnostic (P&D) inspection experiments aimed at improving structural risk assessment, development of self-sensing strategies for monitoring damage precursors, incorporating optimized sensing strategies into P&D systems, and investigating novel approaches for improving rotorcraft

998 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

vehicle maintainability. FY 2016 plans call for the design and development of smart materials that can self-sense, self-heal, and self-reconfigure to facilitate damage/health assessment of aviation component structures, evaluation of material/component damage sensing strategies, modeling and simulation of damage detection, and investigation of data-fusion techniques for assessing material/component failure in aircraft.

Aviation Component Failure Modeling efforts include development of failure analysis and prediction models and techniques to support the Army's "zero maintenance helicopter" concept, including improved failure models to characterize and categorize specific material damage precursors relevant to aviation components, and a probabilistic framework for predicting remaining useful life of vehicle platforms. The work also includes investigation of advanced aviation component health monitoring techniques into health-usage monitoring systems (HUMS) and development of self-sensing structural material technologies that incorporate damage precursor detection philosophy. Planned FY 2016 work will develop the Virtual Risk-informed Agile Maneuver Sustainment (VRAMS) concept, which will evaluate technologies to autonomously provide state awareness at the material level and automate stress-reduction methods; investigate a "virtual reality" concept for self-diagnostics of real-time material state and automated solutions for self-directed maneuver alternatives in real-time; this effort will enable fatigue-free and zero-maintenance aircraft components. **Engine and Drive Train Technology** work includes development of high-temperature materials and improved methods for predicting propulsion system mechanical behavior.

Advanced Technology Development (Budget Activity 3) work relevant to Condition Based Maintenance for aircraft involves efforts in areas similar to those being pursued in basic and applied research projects. The **Advanced Rotary Wing Vehicle Technology** project includes activities intended to mature, demonstrate, and integrate components, subsystems and systems for vertical lift and unmanned air systems that provide reduced maintenance and sustainment costs and enable greater performance through improved rotors, drives, vehicle management systems and platform design and structures. Systems being demonstrated include rotors, drive trains, robust airframe structures, and integrated threat protection systems. This project includes the Joint Multi-Role (JMR) Technology Demonstrator in support of the Future Vertical Lift (FVL) family of aircraft.

Maintainability & Sustainability Systems work is focused on improving the operational availability of rotorcraft while reducing operating and support (maintenance) costs. Specific efforts include component sensing, diagnostics, prognostics, and control systems developments. The *far-term* objective of this work is to enable transition to an ultra-reliable, low-maintenance design approach that significantly reduces unscheduled maintenance, inspections and operating and sustainment costs. Recent and ongoing work has focused on advanced prognostic algorithms for failure modes for engines, structures, rotor systems and drives; the interfaces for health monitoring systems to communicate with Joint Common Architecture standards; integration of system health monitoring with electronic controls to enable adaptive control systems; engine adaptive controls to optimize performance, component life and maintenance schedule based on engine health; multifunctional aircraft

999 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

sensor technology; demonstrating technologies for assessing the structural integrity of a primarily composite airframe; and verifying the integrity of composite repairs and predicting remaining useful life. FY 2016 plans include efforts to demonstrate wireless sensors for on-component processing of part health and usage history; evaluate methodologies enabling probability-of-failure predictions based on vehicle current state and anticipated missions; and mature and demonstrate technologies for component self-assessment, usage tracking and embedded history. Additional work will involve developmental testing of system health and fault recognition algorithms, sensors, and structural global health models. Advanced Technology Development work directed toward maturing integrated CBM technologies that reduce the operation and sustainment costs of vehicle electronics and electrical power devices is being conducted as part of the Army's **Combat Vehicle Electronics** project.

Ongoing RDT&E work in Budget Activities 4 and 5 is more limited than in the other categories, reflecting the fact that much work remains to be done before comprehensive CBM will become common practice for many Army systems. A search of ongoing activities in the Advanced Component Development and Prototypes (Budget Activity 4) category indicates only that the Aviation/Advanced Development program supports an **Advanced Maintenance Concepts and Equipment** project that includes work to develop diagnostics/prognostic monitoring systems. Activities supported in the System Development and Demonstration (Budget Activity 5) category include support under the **Aircraft Avionics** program for the Aircraft Notebook (ACN), an Army aviation automated information system program for streamlining the completion of aviation maintenance activities and the documentation required to maintain airworthiness for all Army aircraft. ACN reduces the information technology footprint within an aviation unit by integrating multiple software applications, including CBM+ tools, onto one hardware platform. The **Automatic Test Equipment** program includes a **Diagnostics/Expert Systems** project that supports the development of test and diagnostic systems and procedures, as well as integration of the Army's Maintenance Support Device (MSD), into the Brigade Combat Team information structure. The MSD serves as the at-platform data collection device for the Army's condition-based maintenance plus (CBM+) initiative and maintains compatibility with emerging aviation platform hardware bus technology, and ACN software interface requirements.

Revised Programs

Certain changes have been made to ARMY RDT&E activities involving CBM since publication of the Fiscal Year 2016 Justification Book of Research, Development, Test & Evaluation, Army, Volumes 1-5. The thrust of Applied Research (Budget Activity 2) involving **Maintainability & Sustainability Technologies** was changed in June 2015 to more accurately reflect work being done on the Autonomous Sustainment Technologies for Rotorcraft Operations (ASTRO) and Ultra Reliable Design programs. The work now involves continuing development of technologies and methodologies to enable more efficient designs and reduce the maintenance burden for future and current fleet vertical lift aircraft; development of on-engine, adaptive engine controls to optimize performance, component life and maintenance schedule based on engine health; development of in-flight, real-time, automated methods to adjust rotor system track and balance to reduce aircraft vibration and loads; development of improved failure

1000 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

detection capabilities within the planetary system; and reducing the size and weight impact of advanced sensor technologies. Additional work involves continuing development of methodology to allow operations above maximum continuous rating for limited periods of time; development of a level of autonomy for the condition assessment process for a composite airframe; decision support for repair decisions with a repair integrity assessment approach; and development of a comprehensive integrated aircraft-wide electrical system capability for diagnostics, fault isolation, and generating trendable health indicators. An assessment directed toward development of reliability criteria for design tools, methodologies, and materials to facilitate optimization of future rotorcraft designs is also being conducted.

Another change, one involving Advanced Technology Development (Budget Activity 3) in the area of **Maintainability & Sustainability Systems,** restates FY 2016 plans as emphasizing the development of technologies and methodologies to enable more efficient designs and reduce the maintenance burden for future and current fleet vertical lift aircraft. Specific planned activities include completion of developments of on-engine, adaptive engine controls to optimize performance, component life and maintenance schedule based on engine health; development of in-flight, real-time, automated methods for adjusting rotor system track and balance to reduce aircraft vibration and loads; development of improved failure detection within the planetary system; and reducing the size and weight impact of advanced sensor technologies. Additional planned FY 2016 work will develop methodology to allow operations above maximum continuous rating for limited periods of time; complete development of a level of autonomy for the condition assessment process for a composite airframe; and provide decision support for repair decisions with a repair integrity assessment approach. This change was also made to more accurately describe the work being done on the ASTRO program.

E.2 Concept Design and Assessment

The Concept Design and Assessment (CD&A) group focuses on

- Multi-disciplinary design analysis and optimization
- Development of design methods and tools
- Concept formulation and design
- Generation of conceptual design performance data to populate the evaluation trade space
- Evaluation of concepts' ability to meet user requirements
- Identification of technology impacts

Figure E-3 summarizes CD&A activities.

CD&A supports in-house AMRDEC efforts, JMR and FVL initiatives, next generation UAS efforts, and other efforts within the Aviation S&T community.

1001 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

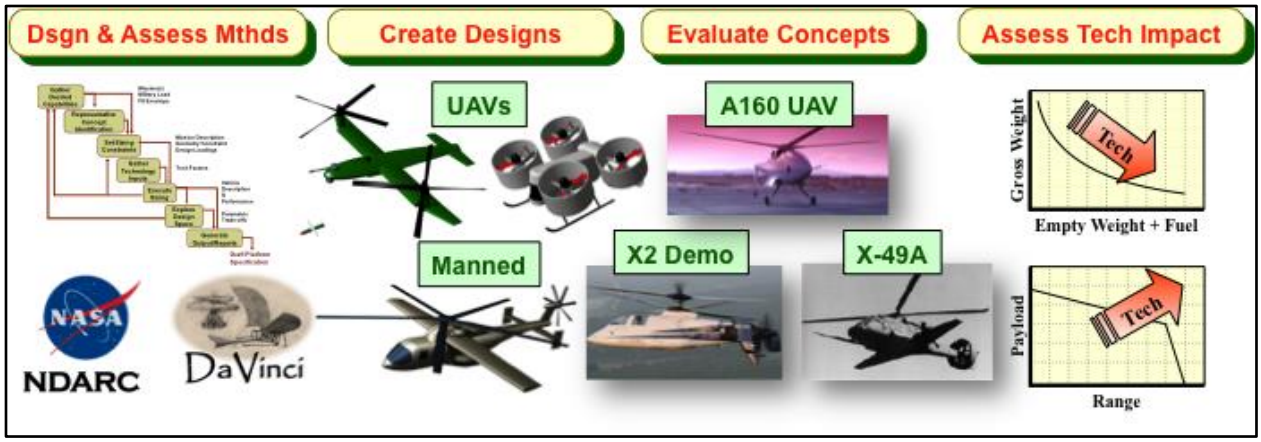

Figure E-3 CD&A Activities

For example, the group has performed extensive analysis for the Future Vertical Lift Initiative to explore the impact of various design choices on projected vehicle performance. These studies inform the requirements definition process to balance requirements across the family of systems. Assessments include aerodynamics, aeromechanics, performance, and flying qualities

In addition, in order to exercise current capabilities, develop new capabilities, and explore new concepts, the group also performs a "deep dive" on an advanced concept such as the tail sitter UAV configuration examined during FY15.

This is a small group (10-15 personnel) that acts as the "honest broker" for many efforts, comparing alternatives and independently assessing claims. Because many of these assessments are competition sensitive they cannot be discussed in this document.

E.3 Unmanned Aircraft Systems

Army Unmanned Aircraft System (UAS) efforts include Manned-Unmanned Teaming (described in Section 3.3) as well as development and modernization of UAS. This section focuses on the latter.

Legacy Army UAS include:

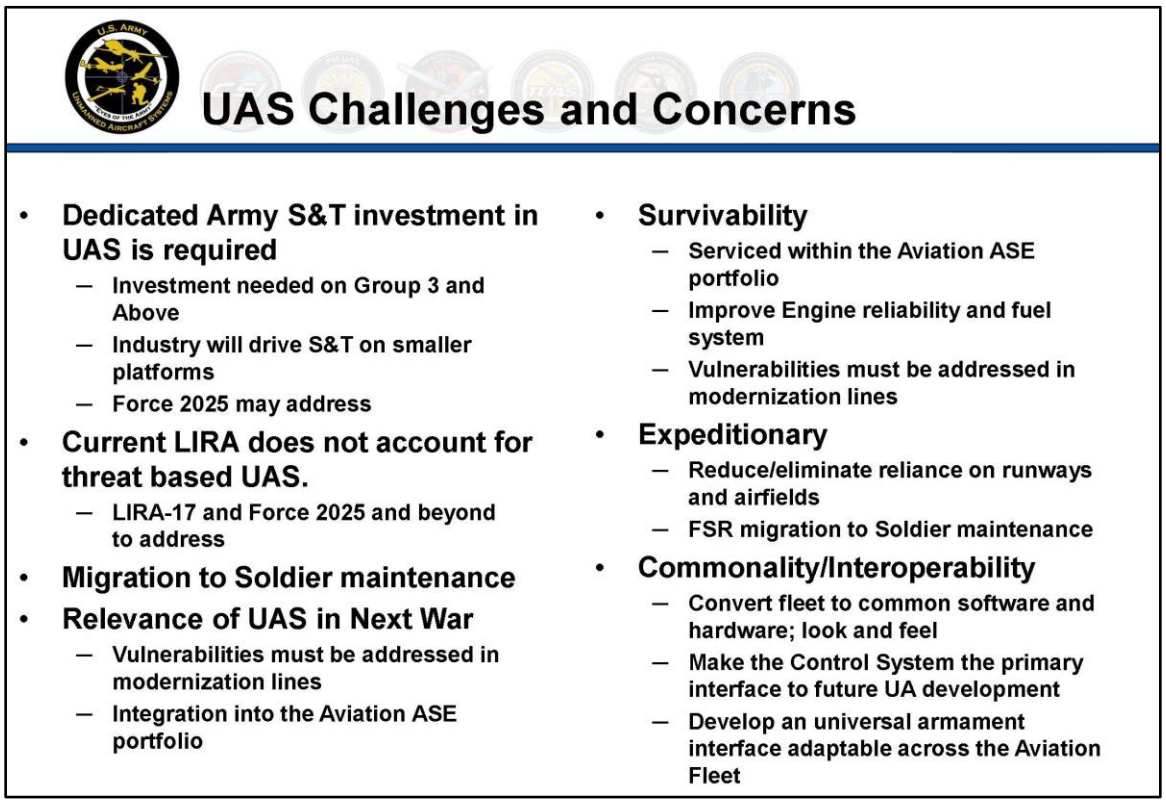
- Raven – hand-launched, 4 lb max takeoff
- Puma – hand-launched, 13.5 lb max takeoff
- Shadow – short range tactical ISR, 375 lb max takeoff
- Gray Eagle – Predator upgrade, 3,600 lb max takeoff

Figure E-4 lists the UAS challenges and concerns cited by the Deputy PM for UAS in July 2015.[37] Note that the first challenge/concern listed is that S&T investment is needed for Group 3 and

[37] John Beck, "Army UAS Update," briefing to Huntsville Aerospace Marketing Association, 15 July 2015, http://hamaweb.org/presentations/2015/july2015johnbeck.pdf

1002 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

above (such as Shadow and Gray Eagle) and that it is assumed that industry will drive the S&T for smaller platforms.



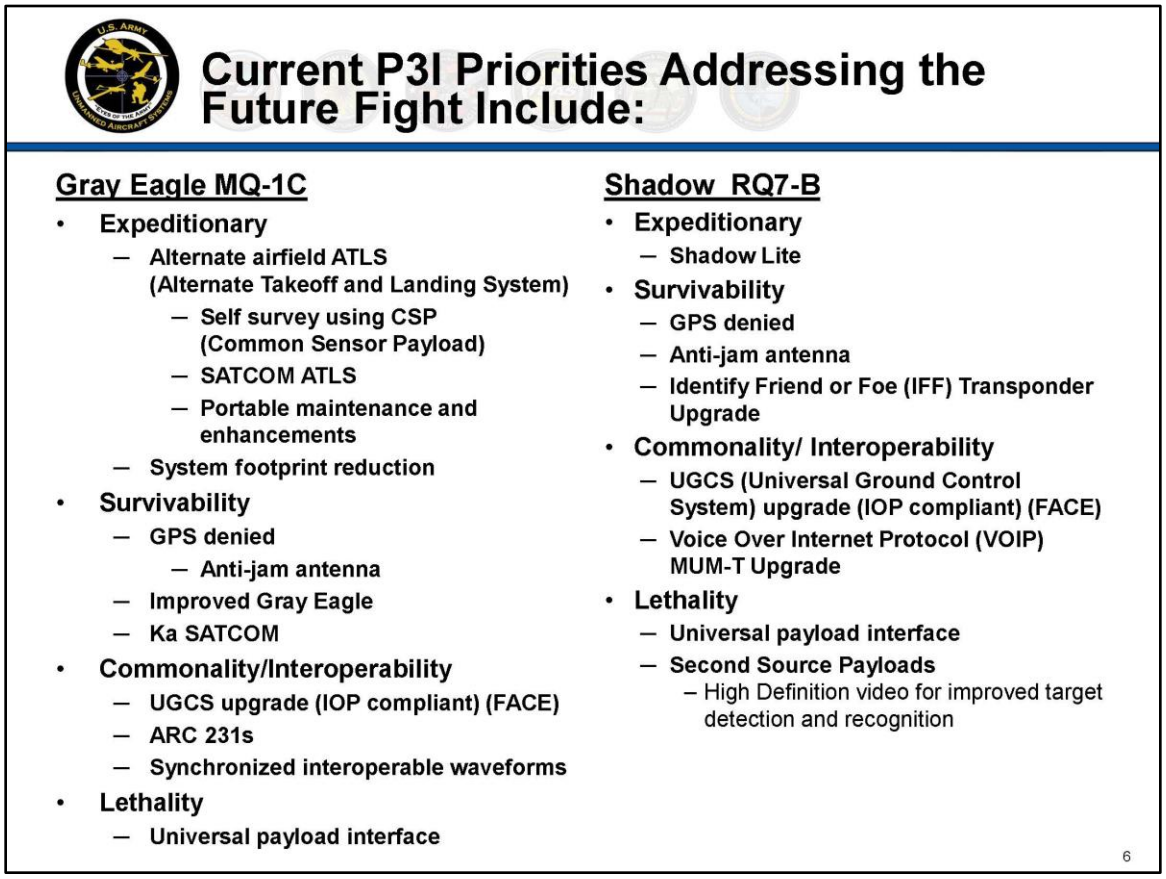


Figure E-4 UAS Challenges and Concerns

The Army P3I priorities to address these concerns for the larger UAS platforms are displayed in Figure E-5. Note that interoperability and commonality are cited for both platforms.

AMRDEC Aviation has been given the responsibility to develop UAS technology for both new systems and modernization of legacy systems, but they have generally not been given additional funds to do so. As a result, Army S&T has relied on industry to develop the UA vehicles. The tendency is for the development companies to build a package that includes both the vehicle and ground control system (GCS), inhibiting development of a common control system. For example, both Shadow and Gray Eagle have unique operating systems and mission packages. While the GCS for Shadow and Gray Eagle is called a Universal Ground Control System (UGCS), it is optimized for one or the other and cannot easily transition to a different vehicle. For example the Gray Eagle GCS has functions to control SATCOM and Link-16 communications, weapons and SAR payloads; the Shadow system does not. An additional complication is that the communications equipment is located in the GCS rather than in the vehicle.

UGCS - Universal Ground Control System
VOIP – Voice over Internet Protocol

Figure E-5 P3I Priorities for Larger Legacy UAS

The US Army Roadmap for Unmanned Aircraft Systems[38] is subtitled "Eyes of the Army" reflecting the Army's current focus on using UAS for ISR. It is anticipated that cargo/sustainment UAS will be introduced in the mid-term (2016-2025). Improved networking will permit improved information distribution in the same timeframe. By the far-term (2026-2035) technology advances will permit operators to control multiple UAS from a common control system.

These considerations led to the ASB recommendation that ASA(ALT) should revise the UAS Roadmap to expand near-term and future UAS vehicle options, some of which should be compatible with speed, hover, and range of current and future manned aircraft, with attributes compatible with distributed functionality among UAS (ISR, Lethality, …).

[38] US Army UAS Center of Excellence, "*Eyes of the Army," U.S. Army Unmanned Aircraft Systems Roadmap 2010-2035*, 2010, http://www-rucker.army.mil/usaace/uas/us%20army%20uas%20roadmap%202010%202035.pdf .

1004 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

E.4 Basic Research

S&T is summarized by REDCOM as:[39]

- **Discovering, Maturing** and **Demonstrating** technologies that support the desired Army (in this case Army Aviation) capabilities and then **combining technologies** into **capabilities.**
- **There are three major types of S&T**
  - **6.1 Basic Research:** Fundamental Science, system non-specific
  - **6.2 Applied Research:** Component Level, Concept Development
  - **6.3 Advanced Technology Development:** System Level, Concept Field Demonstration
- **There are two major strategies**
  - Develop body of technical **knowledge** that supports decisions
  - Develop early versions of **"the system"**

S&T is **not** engineering work for existing platforms. Figure E-6 describes S&T in RDECOM; basic research is distributed between ARL/ARO and the RDECS (AMRDEC for Aviation).

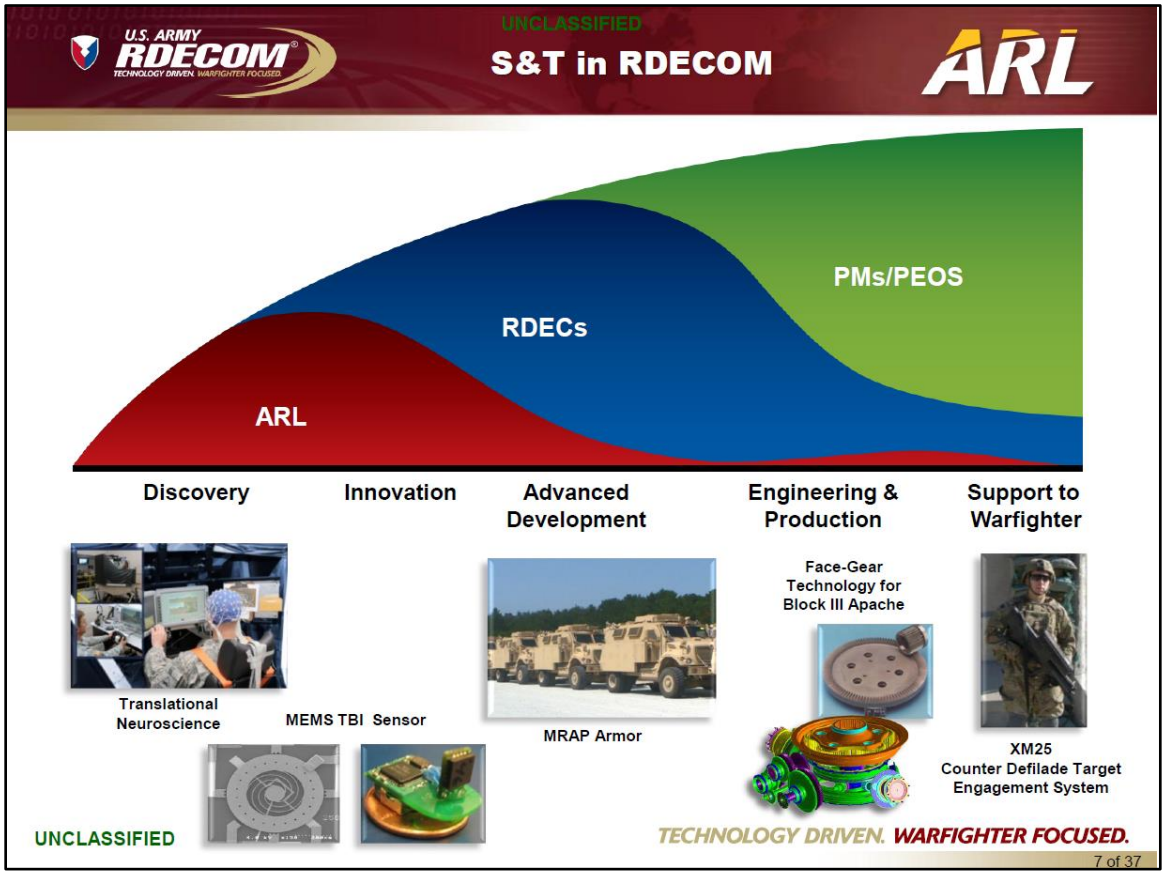

Figure E-6 S&T in RDECOM

[39] Army Aviation Technical Panel briefing to Army Aviation Home-on-Home, 22 January 2015.

1005 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure E-7 shows Aviation S&T and how 6.1 basic research fits within the overall portfolio. The 6.2/6.3 elements shown are discussed in their respective sections within the main body of this report and/or the appendices.

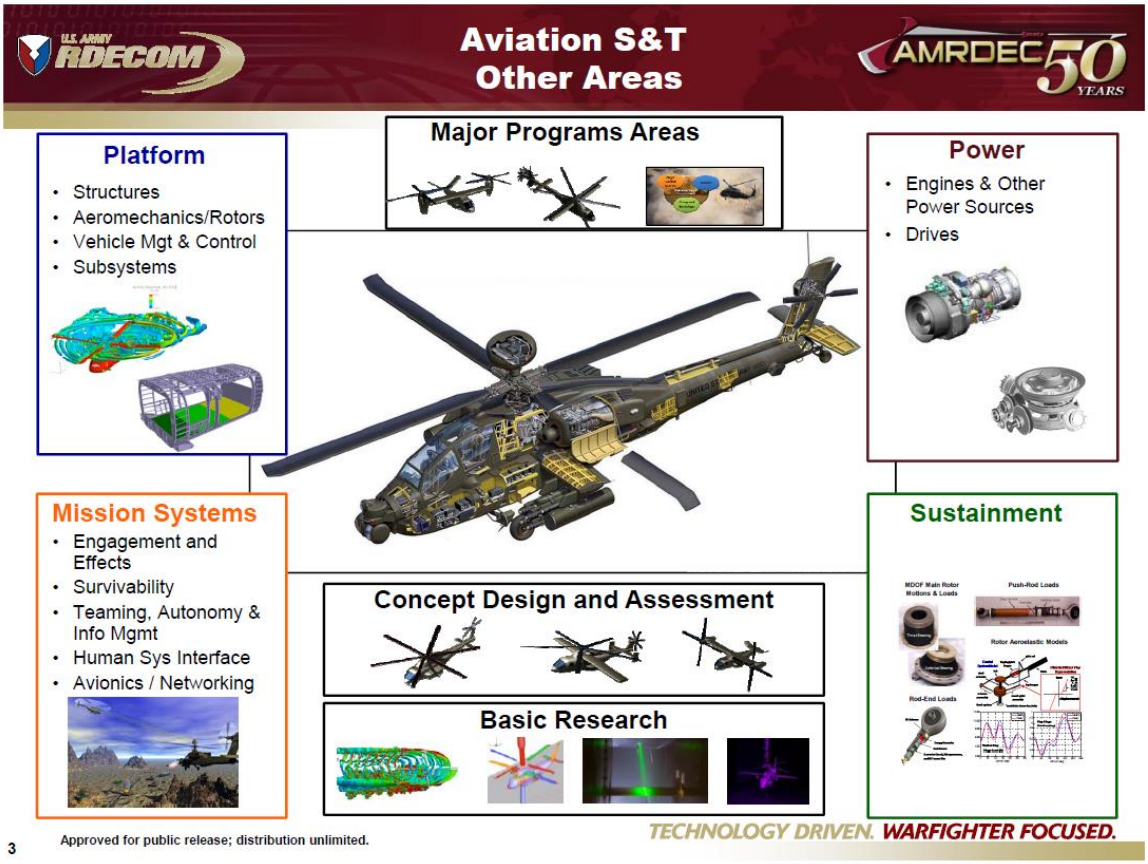

Figure E-7 Aviation S&T - 6.1 Basic Research Supports the Overall Portfolio

Figure E-8 presents an overview of the overall 6.1 Basic research portfolio supporting Army Aviation, distributed across ARL/ARO and AMRDEC including the University Centers of Excellence at Georgia Tech, University of Maryland and Penn State University that combine basic research with graduate education.

Figure E-9 shows a deeper dive into the Aeromechanics elements within the 6.1 basic research portfolio. Figure E-10 presents the aviation 6.1 basic research focus area road map that connects the 6.1 basic research to the 6.2 research areas out to FY 21.

1007 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

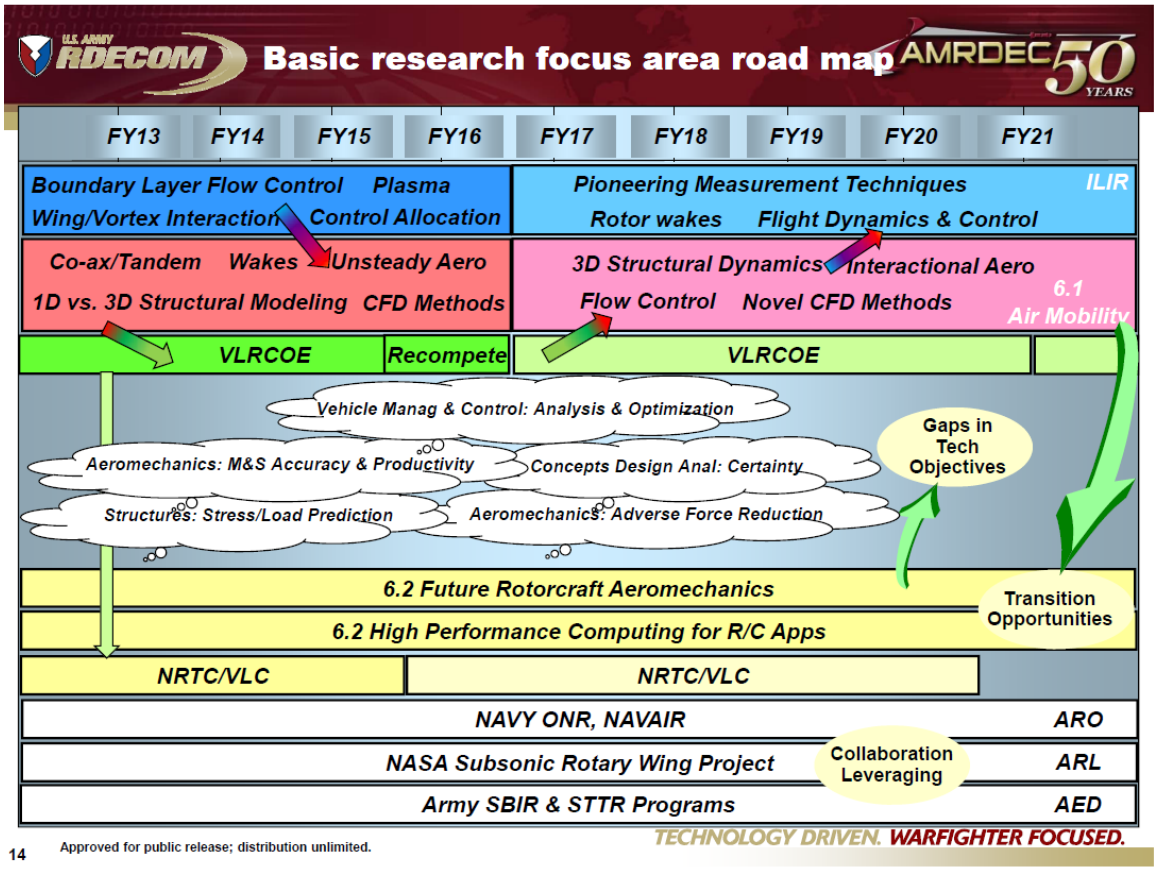

Figure E-10 Aviation Basic Research Focus Area Road Map

Finally, it is important to point out a new laboratory business model termed the "Open Campus Initiative" put forward by ARL. The concept for this ARL initiative is shown in Figure E-11. This innovative approach holds forth the promise of leading to breakthroughs by allowing university/industry researchers extensive access to ARL laboratory facilities and provides an opportunity to have ARL staff work closely with university researchers including faculty, Ph.D. students and post docs as well as industry researchers.

Figure E-11 The ARL Open Campus Initiative

1009 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

APPENDIX F OTHER EFFORTS IN MANNED AND OPTIONALLY MANNED ROTORCRAFT

Task 1 of the TOR directs the study team to review current government and industry aviation plans and programs. Army systems are described in the main part of the report and in Appendix E. The remainder of this section describes the information obtained regarding other efforts on manned and optionally manned rotorcraft.

Figure F-1 summarizes the characteristics of current and near-term DoD rotorcraft with the heaviest platforms at the top. Note that the largest, the King Stallion CH-53K, will be able to lift 35,000 lb and is expected to reach IOC with the Marine Corps in 2018. It is also noteworthy that only two of the remaining rotorcraft, the Osprey and Lakota, have an IOC within the last 25 years.

The Osprey has a cruise speed of 241 kt, the only rotorcraft to exceed 200 kt; it is also the only tilt-rotor on the list.

The Army is funding the only developmental rotorcraft effort in the Services, the Joint Multi-Role Technology Demonstrator (JMR-TD). Two demonstrators are funded for flight tests in 2017. The Bell demonstrator is a tilt-rotor that builds on Osprey technology. The Boeing-Sikorsky demonstrator is a coaxial rigid-rotor, pusher-propulsor design. Both industry teams have invested significant internal resources in the effort. The JMR-TD is described in detail in APPENDIX D.

DARPA is funding the VTOL X-Plane program. Flight demonstrations will take place in 2017-2018. This effort is described in detail in Section F.4

Industry is also funding development efforts in proprietary programs. On 22 May 2015 Sikorsky announced the successful first flight of the S-97 Raider helicopter.[40]

[40]Sikorsky press release, “Sikorsky S-97 RAIDER™ Helicopter Achieves Successful First Flight,” 22 May 2015, http://raider.sikorsky.com/raider-first-flight.asp.

1011 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

F.1 OSD Air Platforms Community of Interest

The Office of Secretary of Defense (OSD) has established 17 Communities of Interest (COIs) to encourage multi-agency coordination and collaboration:

1) Advanced Electronics
2) Air Platforms
3) Autonomy
4) Biomedical
5) CounterIED
6) CounterWMD
7) Cyber Security
8) Electronic Warfare
9) Energy & Power Technologies
10) Engineered Resilient Systems
11) Ground & Sea Platforms
12) Human Systems
13) Command, Control, Comms, Computers, and Intelligence (C4I)
14) Materials & Manufacturing Processes
15) Sensors
16) Space
17) Weapons Technologies

The Air Platforms COI is led by the Air Force. The Army principal is Bill Lewis of AMRDEC.

COIs develop technology roadmaps for the relevant technology areas and describe the cross-organization interactions in terms of four levels of coordination:

1) Information Sharing
2) Active Coordination (deconflicted, not joint)
3) Building Joint S&T Roadmaps
4) Delivering Joint S&T Roadmaps

The Air Platforms COI is primarily Level 2 (for technologies that are predominantly single-Service investment) and Level 3 (for technologies of common interest).

Air Platform Technology Sub-Areas are 1) Fixed Wing Vehicles, 2) Rotary Wing Vehicles, 3) High Speed/Hypersonics, and 4) Aircraft Propulsion, Power and Thermal. In the funding request for FY16 $207M is planned for S&T in rotary wing vehicles. The Army provides over 60% of the proposed S&T funding for rotary wing vehicles; DARPA plans to provide over 20% and the Navy/Marine Corps will provide over 10%. OSD plans to provide a small amount for rotary wing S&T (on the order of $350K). Specific OSD projects were not identified.

F.2 Navy/Marine

The USN and USMC operate a number of manned vertical lift platforms for a variety of missions. Among these are the AH-1, UH-1, VH-3, HH-60, M/SH-60, C/MV-22 and CH-53. Of most interest to potential Army aviation applications are the V-22 and CH-53K.

1012 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The V-22 Osprey Tilt-Rotor, with a speed of approximately 250 knots, is the only deployed vertical lift platform within the DoD inventory with a speed that can satisfy the FVL requirement. In fact, the V-22 tilt-rotor technology provides the basis for one of the JMR-TD vehicles, which will demonstrate FVL aerodynamic capabilities, including speed. While V-22 does not satisfy other FVL requirements, it could serve as a back-up interim capability for the most speed-critical FVL missions (e.g., MEDEVAC) in the event of unanticipated programmatic delays to the FVL program. In addition, some of the V-22 technology efforts could be of benefit to Army aviation rotorcraft systems. These include material efforts, such as rotorcraft blade coatings, engine blade wear coatings and windscreen coatings. Relevant aerodynamic technology efforts include active flow control and external carry at high speeds. AMRDEC is tracking these S&T efforts to exploit advances relevant to Army aviation.

The Army CH-47F currently has the greatest vertical lift load capacity of Army deployed platforms, rated at 14 stons. However, at hot/high conditions, the external load is 6 stons at 20 nm. As is shown in Figure F-2, this load capacity can be greatly improved to 9 stons at 20 nm with a future upgrade to the Future Affordable Turbine Engine (FATE).

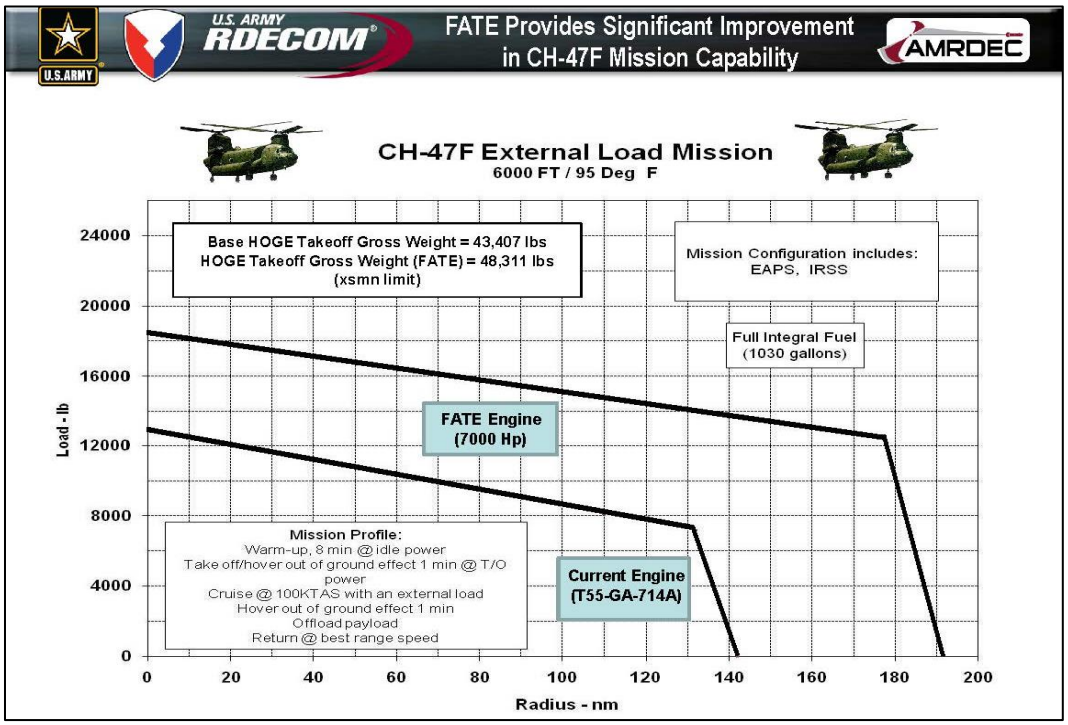

Figure F-2 Future Affordable Turbine Engine Improvement for CH-47

The latest version of the USN CH-53, the CH-53K, has an external load capacity of 18 stons. The requirement is for an external load capability of 15 stons at 110 nm (Figure F-3). While 18 stons is still shy of the Joint Heavy Lift (JHL) requirement of 20-30 stons, the CH-53K could provide the Army with a significant increase in heavy vertical lift capability if it becomes evident that a JHL

1013 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

program is unaffordable anytime in the foreseeable future. From an S&T perspective, the Army should benefit from technologies being developed for CH-53K (Figure F-4).

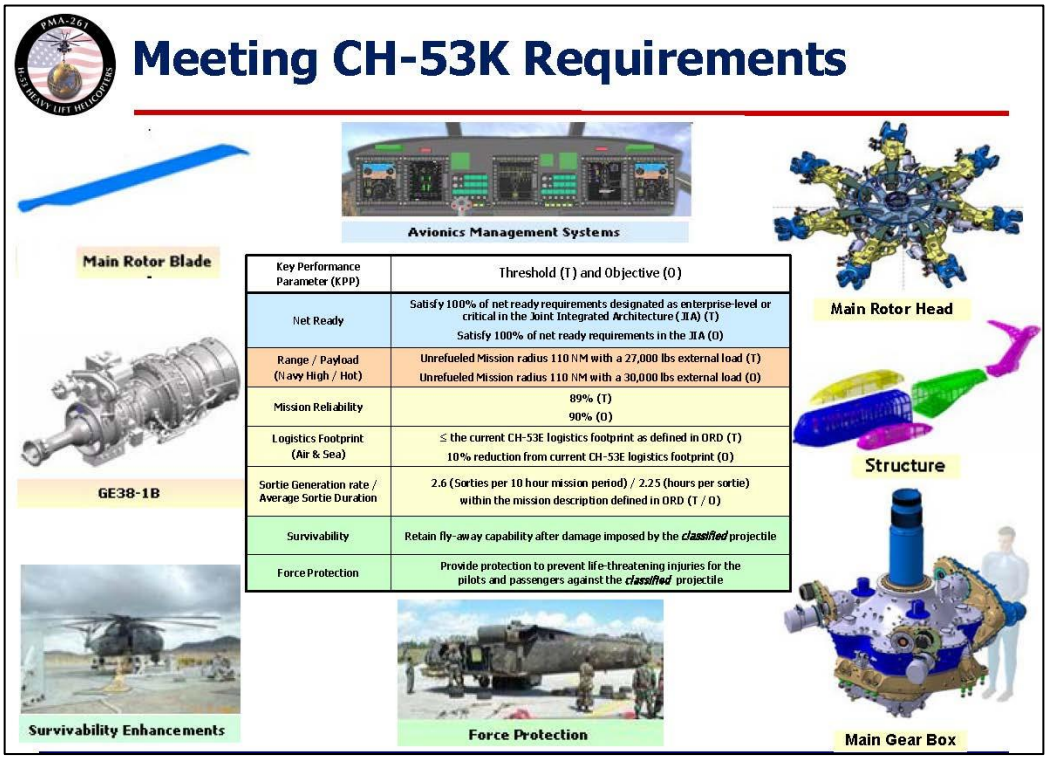

Figure F-3 CH-53 Requirements

Figure F-4 CH-53K Science and Technology

F.3 Air Force

Beginning with the Key West Agreement[41] in 1948, there have been numerous documents that define the separate responsibilities of the Army and Air Force with respect to air transport. The Air Force has responsibility for longer-range transport and has chosen to use fixed wing aircraft for the purpose.

An Air Force presentation to the House Armed Services Committee on Air Force Rotorcraft Programs[42] stated:

> Air Force rotary wing assets are critical to the mission of the Air Force and provide worldwide support to Combatant Commanders. The HH-60G supports the Service's Core Function of Personnel Recovery. Additionally, the UH-1N provides security for Nuclear Operations while also ensuring continuity of government and continuity of operations in the National Capital Region. Another H-1 variant, the TH-1H, provides a modern platform for the rotary wing track of

[41] Richard Wolf, *The United States Air Force: Basic Documents on Roles and Missions*, 1987, http://www.afhso.af.mil/shared/media/document/AFD-100525-080.pdf

[42] Kane, Major General Robert and Major General Noel Jones, *Presentation to the House Armed Services Committee, Subcommittee on Tactical Air and Land Forces – Air Force Rotorcraft Programs*, 27 March 2012, http://armedservices.house.gov/index.cfm/files/serve?File_id=d305f5a9-ce63-4b12-b815-3a459128ea9e

> Air Force undergraduate pilot training. Finally, the CV-22 provides US Special Operations Command with a unique long-range vertical lift capability.
> . . .
> The Air Force continues to participate in the DoD-wide Future Vertical Lift effort to ensure a joint roadmap informs future modernization efforts. While fiscal constraints may have required us to reassess the timing of some rotary wing modernization efforts, the Air Force's commitment to rotary wing modernization remains strong.

Thus there are several niche roles for rotary wing aircraft in the Air Force. In general the Air Force adapts aircraft developed by another Service.

F.4 DARPA

DARPA is currently funding the Vertical Takeoff and Landing (VTOL) Experimental Aircraft (X-Plane) effort. This $130 million project will cover 52 months, from 2013 to 2018, in three phases:

- Phase 1: develop a preliminary concept design for aircraft (4 primes)
- Phase 2: develop, construct, and integrate (1 prime)
- Phase 3: conducting flight test demonstrations by 2017-2018 (1 prime)

Conventional rotorcraft are limited to about 175 knots. Fixed wing aircraft achieve higher speeds but are not as agile as a helicopter. The DARPA effort has four specific goals:[43]

- Speed: Achieve a top sustained flight speed of 300 kt-400 kt
- Hover efficiency: Raise hover efficiency from 60 percent to at least 75 percent
- Cruise efficiency: Present a more favorable cruise lift-to-drag ratio of at least 10, up from 5-6
- Useful load capacity: Maintain the ability to perform useful work by carrying a useful load of at least 40% of the vehicle's projected gross weight of 10,000-12,000 pounds

The effort focuses on unmanned aircraft but technology developed is applicable to manned aircraft as well.

The four competing designs in Phase 1 are shown in Figure F-5: [44]

- Boeing Phantom Swift – Four ducted fans - 2 body lift fans fore and aft and 2 wingtip thrusters that tilt for forward flight
- Karem – tilt rotor with optimum speed rotor
- Sikorsky (w/ Lockheed Skunk Works) – tail-sitter aircraft using rotor blown wing

1016 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- Aurora Flight Sciences Lightning Strike – electric generators that drive 24 fans that tilt upward for lift and forward for horizontal flight, 18 are in a wing near the tail of the aircraft and 6 are on a canard near the nose

Downselect from four contractors to one is expected late 2015/early 2016.

Figure F-5 DARPA VTOL X-Plane Designs

F.5 Army Special Operations

In addition to Chinook and BlackHawk, Army Special Operations uses the AH-6/MH-6 Little Bird attack/utility helicopter shown in Figure F-6. Little Bird is used for close air support of ground troops, target destruction raids, and armed escort of other aircraft. It is a small (3,100 lb max takeoff) aircraft that is less detectable than the larger platforms.

1017 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure F-6 Little Bird carrying Rangers strapped to benches along the fuselage.

F.6 NASA

The Revolutionary Vertical Lift Technology Project (RVLT) is part of the overall NASA Advanced Air Vechicles (AAV) which is shown in Figure F-7. Other projects within the AAV Program, including the Advanced Air Transport Project, the Advanced Composites Project and the Aeronautical Evaluation & Test Capabilities Project, provide some peripheral basic support for the RVLT project.

1018 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

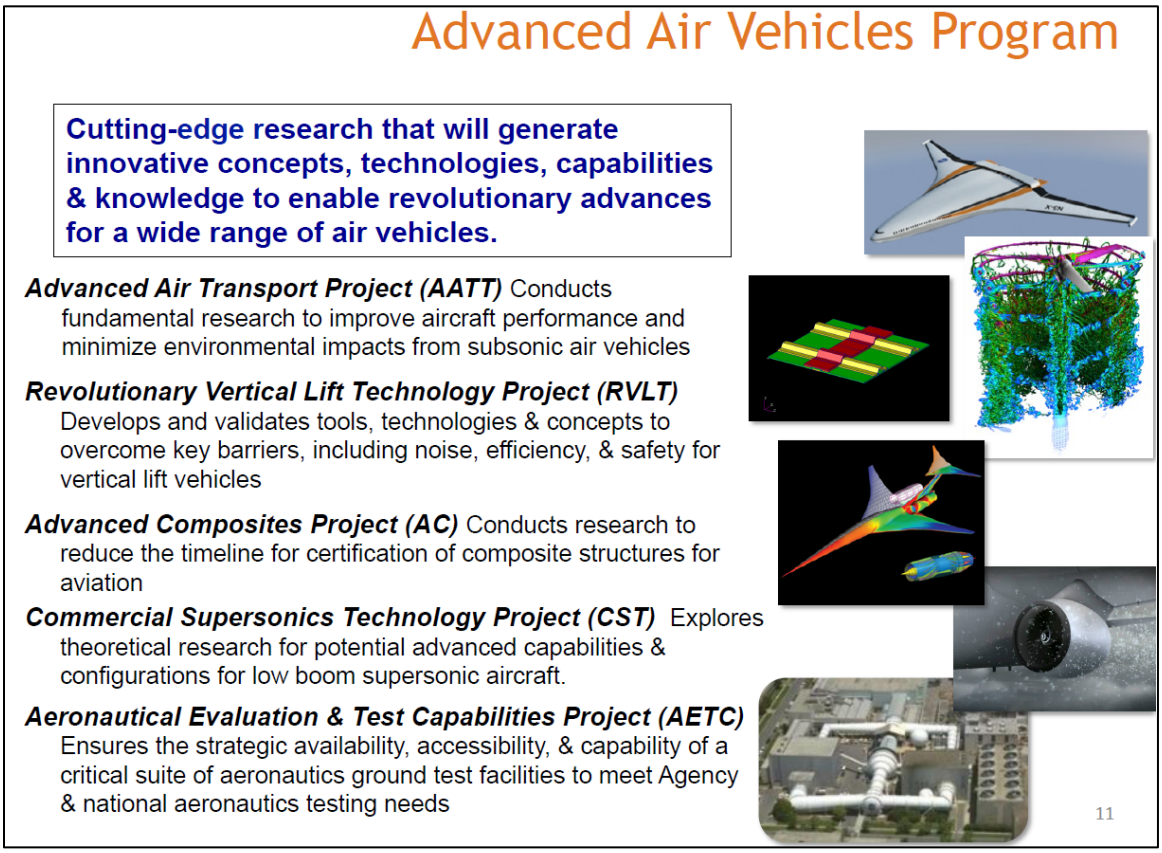

Figure F-7 NASA Advanced Air Vehicles Program

Figure F-8 shows the future capabilities that the RVLT project contains which supports the development and validation of tools, technologies and concepts to overcome key barriers for Vertical Lift Vehicles. These key challenges are shown in Figure F-9

The vision of the RVLT project is to enable the development of vertical lift vehicles with aggressive goals for efficiency, noise, and emissions to expand current capabilities and develop new commercial markets. The scope of the RVLT project is two-fold:[45]

1. Development of conventional and non-conventional very light, light, medium, heavy and ultra-heavy vertical lift configurations.
2. Development of technologies that address noise, performance, efficiency, safety, community acceptance and affordability. These include:
    a. Advanced Efficient Multi-speed Propulsion: Demonstrate and mature propulsion and drive system technologies to enable increased vehicle speeds while maximizing propulsive efficiency and minimizing weight penalty. Figure F-10 shows the development schedule through FY20 for this technology.

1021 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure F-11 provides an overview of the interaction between NASA and DoD. This has been a very effective relationship that has been ongoing for 50 years. The challenge for rotorcraft R&D is that NASA's funding levels are ~$20M per year (includes salary for ~65 Civil Service Workers) and similar levels of funding are anticipated for FY16-20. This relatively limited investment by NASA is already highly leveraged by the Army and supports the ASB Study Teams Recommendation 9, advocate more funding for Aviation S&T.

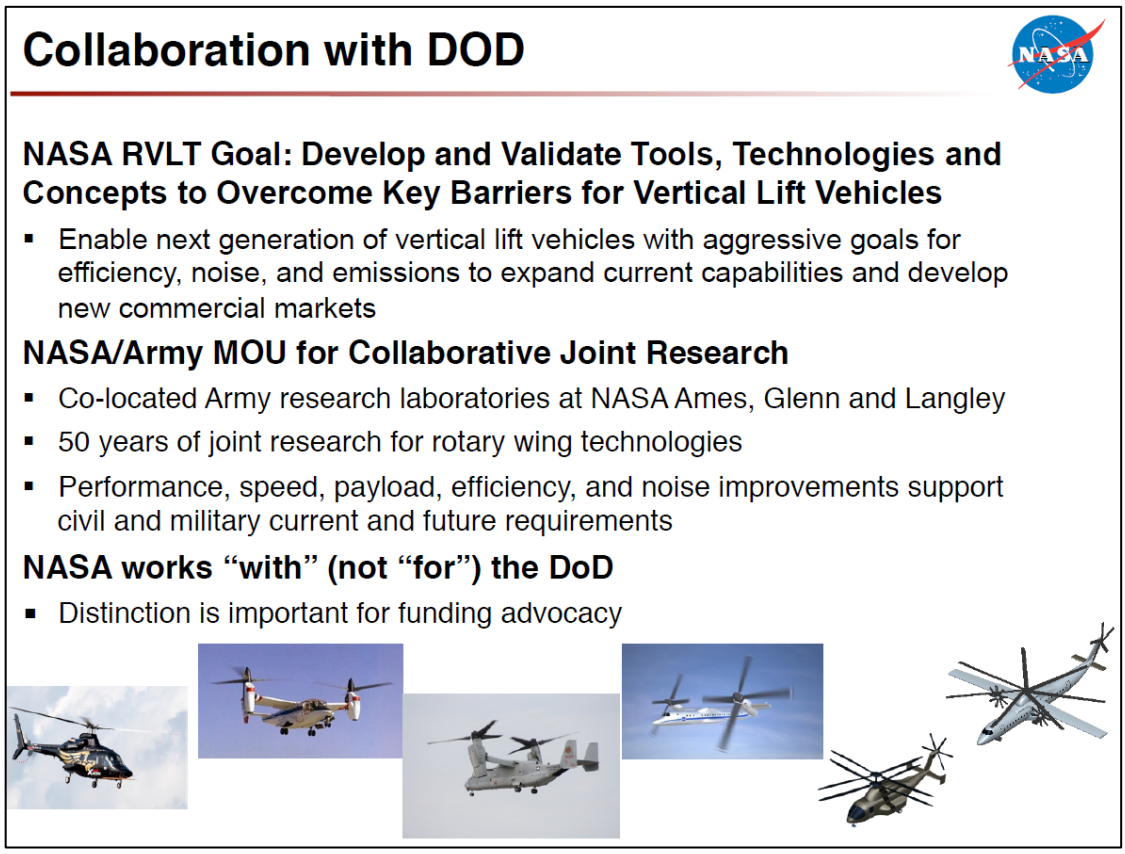

Figure F-11 Overview of the Interaction between NASA and DoD

F.7 Industry

Industry teams support Army aviation in the modernization of legacy rotorcraft systems and the development of new systems. For legacy systems, Sikorsky and its contractor team works closely with PEO-Aviation, AMRDEC and CERDEC in development of the UH-60 modernization roadmap and performs the development and production of upgrades under contract to PM UH-60. Likewise, the Boeing Company and its contractor team actively support the Army in modernization of AH-64 and CH-47. In both cases, the contractors work closely with RDECOM laboratories to develop technologies for insertion into the platforms. They also often invest company funds into technologies that may enable improved operational effectiveness or reduced operations and support costs for future upgrades of the systems.

1022 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Industry also invests in the development of new aviation systems and capabilities that may lead to future Programs of Record (PORs). A perfect example is the JMR-TD, in which the industry teams are more than matching Army S&T investment. Likewise, several industry teams are investing in the DARPA X-plane program and in USN/USMC rotorcraft developments.

Rotorcraft prototyping programs are particularly important to the health of the US military rotorcraft industry because new PORs are too infrequent to maintain design and development skills. The decline of US market share in the commercial helicopter market provides evidence that US leadership in rotorcraft system design and development is eroding. As indicated in Figure F-12, the total share of US industry ***combined*** is only 25%, while the two European companies, Airbus Helicopters and Augusta Westland have almost 60% of the world market.

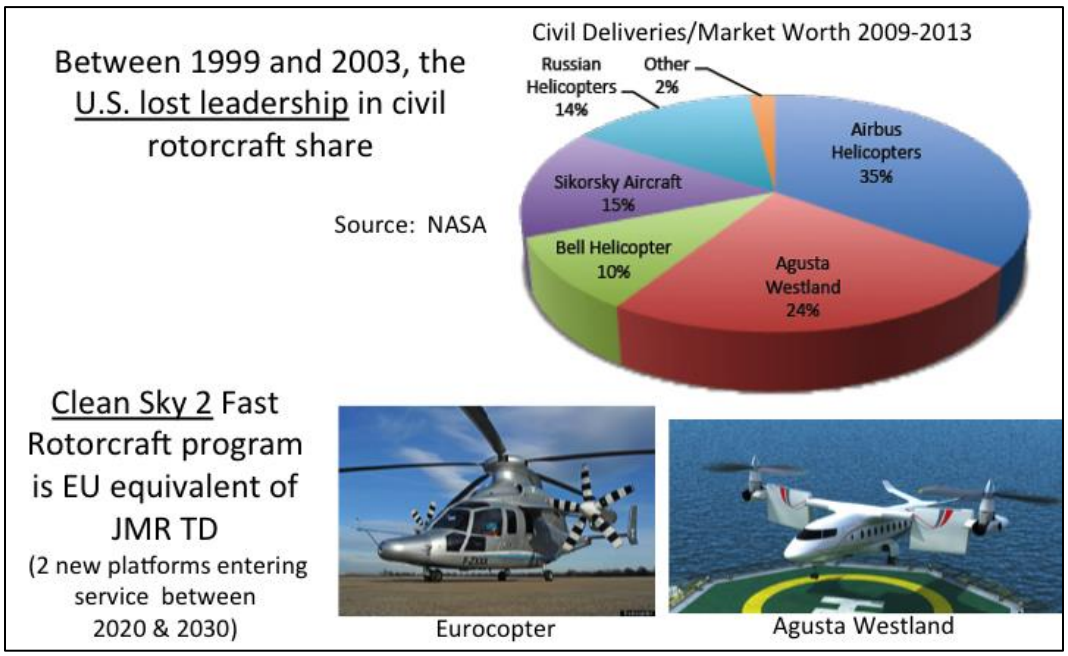

Figure F-12 Worldwide Competition

Concern regarding the health of the US rotorcraft industry has been voiced by the Vertical Lift Consortium (VLC). The VLC was established in 2009 in response to a memorandum from the Under Secretary of Defense AT&L that stated that the Future Vertical Lift initiative "will only be successful with the full support of, and partnership with, the vertical lift aircraft industry". The mission of the VLC is to "work collaboratively with the US Government to develop and transition innovative vertical lift technologies to rapidly and affordably meet warfighter needs." Its mission is to be a "cohesive national resource which various Government customers can efficiently access for innovative technologies to fulfill critical DoD vertical lift needs, which invigorates the US industrial base, drives innovation, and achieves an international competitive edge."

In its response to the FVL Executive Steering Group (ESG), the VLC indicated that the US has enjoyed global asymmetrical advantage from innovative technology that has been generated by a diverse, competitive research and industrial base and motivated by an engaged Government

1023 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

customer. However, continued advantage is not assured and Asia and Europe are at par and advancing.

Among the programs being sponsored by the European Union is the Clean Sky 2 Fast Rotorcraft Program, which has performance attributes similar to FVL and which is building two prototypes very similar to JMR-TD. A robust US rotorcraft industry is essential for the future of Army aviation, but that is certainly not assured in this global environment.

1024 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

APPENDIX G ONGOING AND PLANNED DEVELOPMENT FOR UAS (INLCUDING MUM-T)

Task 1 of the TOR directs the study team to review current government and industry aviation plans and programs. Army Unmanned Aircraft Systems (UAS) are described in APPENDIX E. The remainder of this section describes the information obtained regarding other unmanned aircraft systems, both fixed wing and rotary wing as well as efforts in manned-unmanned teaming (MUM-T).

Figure G-1 provides definitions of the grouping used to describe DoD UAS, primarily based on size. Group 1 systems are handheld, operate at low altitude, and used by small units; Group 5 systems are high altitude platforms.

	Group 1	**Group 2**	**Group 3**	**Group 4**	**Group 5**

G.1 DoD Unmanned Systems Integrated Roadmap

The Unmanned Systems Integrated Roadmap (FY2013-2038)[46] describes the role of unmanned systems to meet the mission and capability needs of Combatant Commanders as follows:

> There are no requirements for unmanned systems within the Joint force, but some capabilities are better fulfilled by unmanned systems. Unmanned systems provide persistence, versatility, survivability, and reduced risk to human life, and *in many cases are the preferred alternatives especially for missions that are characterized as dull, dirty, or dangerous.* With that mindset, unmanned systems are being optimized for these dull, dirty, or dangerous missions:
>
> - Dull missions are ideal for unmanned systems because they involve long-duration undertakings with mundane tasks that are ill suited for manned systems. Good examples are surveillance missions that involve prolonged observation. Unmanned systems currently fulfill a wide variety of "dull" mission sets, and the number will increase in all domains as unmanned systems capabilities improve.
> - Dirty missions have the potential to unnecessarily expose personnel to hazardous conditions. A primary example is chemical, biological, and nuclear detection missions. Unmanned systems can perform these dirty missions with less risk exposure to the operators.
> - Dangerous missions involve high risk. With advances in capabilities in performance and automation, unmanned systems will reduce the risk exposure to personnel by increasingly fulfilling capabilities that are inherently dangerous.

The roadmap summarizes mission and capability needs, technology areas of interest, operating environments, logistics and sustainment challenges, training challenges, and international issues for unmanned air, ground, and maritime systems.

G.2 Navy/Marine

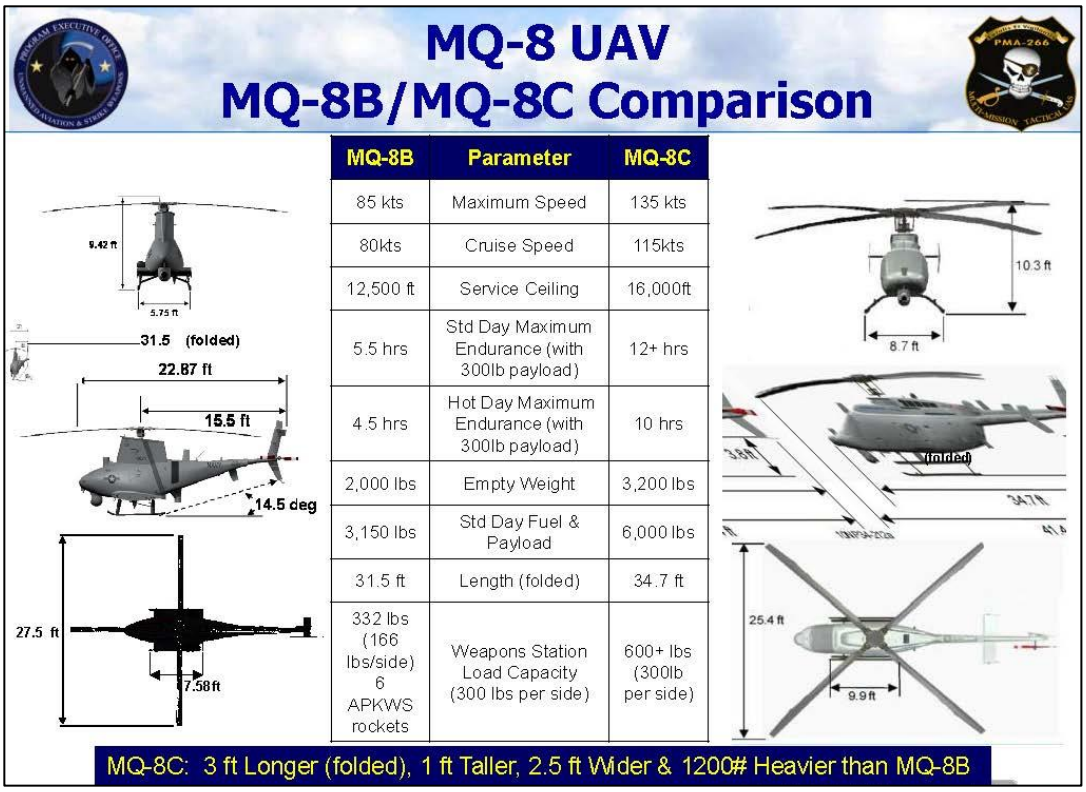
Among the UAVs in the USN/USMC inventory are the RQ-11B Raven, the RQ-12A Wasp, the RQ-20A Puma, the RQ-7B Shadow, the RQ-21A Blackjack, the MQ-8 FireScout, and KMax.

The Raven, Wasp and Puma systems are small man-packable/portable systems used for organic, real-time Reconnaissance, Surveillance and Target Acquisition (RSTA) and Bomb

[46] Department of Defense, "Unmanned Systems Integrated Roadmap (FY2013-2038)," DOD-USRM-2-13, 2013, http://www.defense.gov/Portals/1/Documents/pubs/DOD-USRM-2013.pdf , p20.

1027 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Damage Assessment (BDA) at the small unit (battalion and below) level. Among these, the Raven and Puma systems are also operated by the Army. The Shadow is also deployed by the Army, for ISR missions.



The RQ-21A Blackjack (Figure G-5) is a larger twin-tailed follow-on to the ScanEagle UAS, with a payload capacity of 39 lb. and an endurance of 16 hours. It is currently used for RSTA data collection and dissemination. Standard payloads include day/night full motion video; electro-optical/infrared cameras; mid-wave infrared imager; laser rangefinder; and communications relay. Mission flexibility is allowed by a modular payload bay for payload swap out and integration of advanced payloads. Among the mission system payloads in development for Blackjack are SIGINT, EW and SAR/GMTI. This modular payload feature and the types of modular mission payloads in use or in development are the types of capabilities for the UAVs that complement manned assets envisioned for the distributed functionality system-of-systems concept discussed in section 2.3 of the report.

Figure G-5 RQ-21A Blackjack and Launcher on the flight deck of USS Mesa Verde

The USN/USMC operates two unmanned rotorcraft systems, the MQ-8 FireScout and the CQ-24A KMAX. The MQ-8C is a 3000 lb. class unmanned rotorcraft capable of carrying a 300 lb. payload for up to 12 hours (Figure G-6). The KMAX was used by the USMC for unmanned cargo delivery in OEF. It is capable of carrying up to 4500 lb. of payload per sortie (Figure G.2-3). The Army currently lacks a vertical lift UAV for point-of-need sustainment to distributed forces. The KMAX might be able to provide an interim capability until the Army can afford a more tailored solution to this need.

1028 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

MQ-8B	Parameter	MQ-8C

G.3 Air Force

The Air Force vision depicted in Figure G-8 shows the Unmanned Combat Air Vehicle (UCAV) flying in close formation with the F-22, providing "wingman" capabilities utilizing autonomous operations under supervised control of the manned fighter.

Figure G-8 Air Force Vision

The Air Force UAS portfolio focuses on larger platforms (over 1320 lbs):

- MQ-1 Predator/Gray Eagle
- MQ-9 Reaper
- RQ-4A and RQ-4B Global Hawk

The objective of the Low-Cost Attritable Aircraft Program is to develop mission-capable low-cost aircraft concepts and prototypes to validate technologies required for rapid and agile production. The program is scheduled for spiral development with flight demonstrations by FY21.

1030 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

G.4 DARPA

DARPA has several UAS and/or MUM-T projects, including System of Systems Integration Technology and Experimentation (SoSITE), Collaborative Operations in Denied Environment (CODE), and Aerial Reconfigurable Embedded System (ARES).

Systems of systems aviation architectures, utilizing both manned and unmanned assets which are carefully networked with dispersed functionality, offer the potential to quickly and more effectively respond to a new world of complex mission threat scenarios. This hypothesis is currently being tested at DARPA in the SoSITE program depicted in Figure G-9.

DARPA, through its SoSITE innovative research program, is attempting to demonstrate that a system of systems (SoS) approach can:

1. Provide increased military effectiveness in complex environments,
2. Obtain cost leverage (i.e., the cost of the opponent to counter relative to the cost of the US to deploy), and
3. Enable adaptability necessary to maintain US air superiority in contested environments.

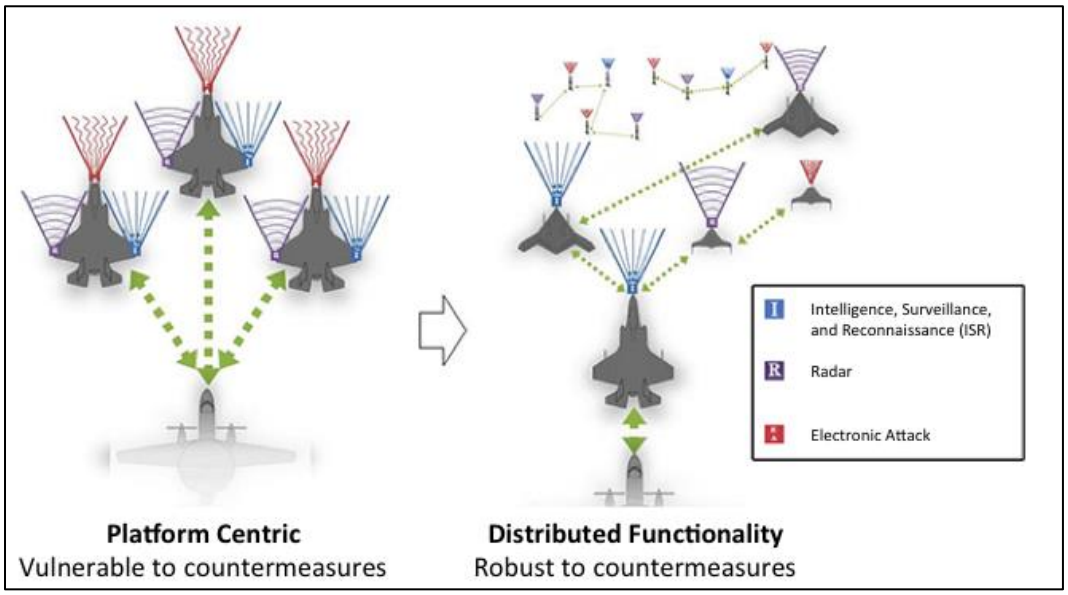

Figure G-9 System of Systems Integration Technology and Experimentation (SoSITE)

The objective of Phase 1 of this DARPA program is to develop architectures for distributing functionality across networks of manned and unmanned platforms for future experimentation, and to develop tools to enable this distribution to be done quickly and reliably. The second phase of the SoSITE program will focus on resolving risks through experiments.

Anti-access, aerial denial (A2/AD) scenarios developed by the DoD are being used as the bases for simulating and evaluating a host of solutions sets using existing, developing and next-generation technologies. Contracts with Boeing, General Dynamics, Lockheed Martin, Northrop Grumman, Apogee Systems, BAE Systems, and Rockwell Collins are experimenting with ways to spread capabilities across a number of manned and unmanned vehicles and weapons to

1031 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

address the future threat scenarios. The SoSITE project encompasses the integration of aircraft, weapons, sensors, and mission systems via the SoSITE open-systems architecture (OSA). The program OSA is based on the open mission systems (OMS) -- an Air Force effort which developed interfaces between mission systems and services connected through an avionics service bus. (The interfaces are based upon a set of open and standardized interface definitions.)

The DARPA Collaborative Operations in Denied Environment (CODE) program depicted in Figure G-10 is another example of research investigating system of system approaches for distributing capabilities among a team of UAVs. This effort is considering how to enable UAVs to work together in teams and take advantage of the relative strengths of each participating unmanned aircraft. The program is specifically looking at expanding the mission capabilities of existing UAVs through increased autonomy and inter-platform collaboration. DARPA's premise is that collaborative autonomy has the potential to increase capabilities and reduce costs of today's UAVs by composing heterogeneous teams of UAVs that can capitalize on the capabilities of each unmanned aircraft without the need to duplicate or integrate capabilities into each UAV.

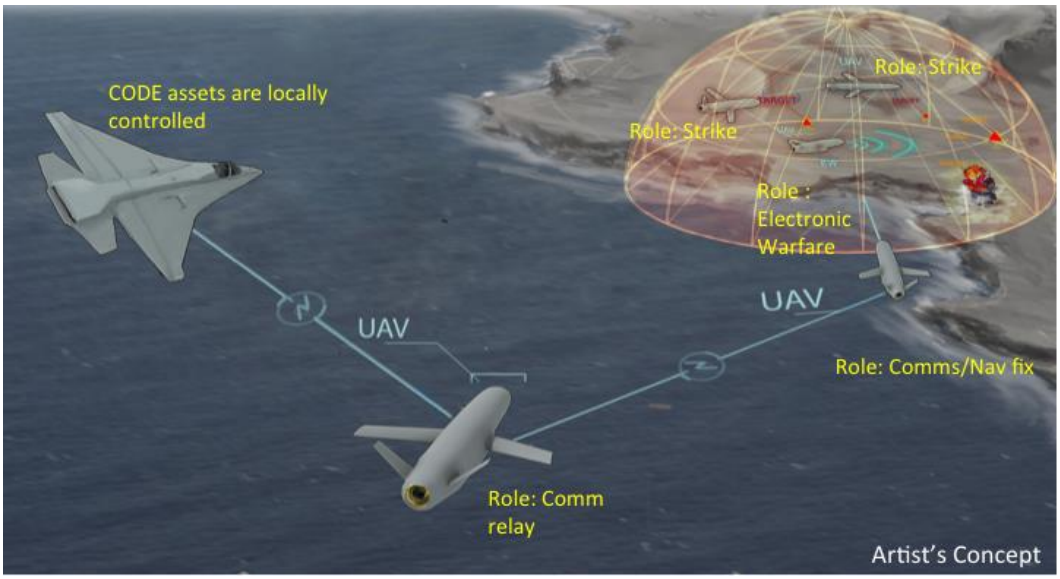

Figure G-10 Collaborative Operations in Denied Environment (CODE)

A SoSITE type approach could have significant utility in Army aviation mission planning. The threat environment for Army aviation is becoming much more complex with a host of different technology threats surfacing (as illustrated in Figure G-11) which include the potential of attack by: cyber, directed energy weapons, sophisticated MANPADS, swarms of UAVs, and the electromagnetic spectrum. A distributed platform/system approach rather than a platform centric design offers the potential of realizing higher survivability under these complex conditions and an increased potential for successful mission execution.

1032 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure G-11 Complex Threats

The Army's Future Combat System (FCS) had a vision of creating a highly, integrated systems-of-systems network which could flexibly adapt to complex environments. However, after the program's cancellation, the vision of creating distributed system-of-system networks lost priority and a platform-centric approach has largely prevailed. This is evident in the Future Vertical Lift demonstrator programs. There is clearly some good work being done on this effort to reduce program risks associated with a new platform development; however, we see little discussion about how these future platforms can be teamed with other unmanned assets or how functions could be distributed among other platforms to achieve higher potentials of mission success, increased survivability and lower overall lifetime costs.

The panel believes that networked systems studies need to be intensified in the Army especially with regard to aviation mission planning. MUM-T (manned-unmanned teaming) exercises are a first step and are critical to demonstrating such things as interoperability among unmanned systems through the Universal Ground Control Stations and highlighting open architectural approaches that allows multiple control nodes and information access points via the Tactical Common Data Links (TCDL). However, research efforts similar to the SoSITE program at DARPA need to be increased using Army's common open architecture protocols to model and experiment with integration of different technologies and assets in different mission configurations. Other elements such as secure communications technologies, levels of autonomy, common ground controls and operating conditions (visually denied or GPS denied environments) need to be included in these modeling scenarios. The utility of employing unmanned assets used as attritables (Air Force/DARPA construct) should also be considered. While these attritable unmanned systems are not designed to be expendable, meaning that

1033 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

they are not intended to be lost every time they are sent out, they are "attritable," meaning that the operator can afford to "attrit" or lose them, especially when the alternative is the loss of a manned aircraft or an aircrew.

ARES is a vertical takeoff and landing (VTOL) flight module designed to operate as an unmanned cargo platform capable of transporting a variety of payloads. The ARES VTOL flight module is designed to have its own power system, fuel, digital flight controls and remote command-and-control interfaces. Twin tilting ducted fans would provide efficient hovering and landing capabilities in a compact configuration, with rapid conversion to high-speed cruise flight. Lockheed-Martin is the primary performer. The goal is a 7,500 lb vehicle that carries a 3,000 lb payload externally. It can land in a 50x50 ft area. It could be used for MEDEVAC if it is rated to carry humans. Flight test is scheduled for 4Q 2015.

Figure G-12 Aerial Reconfigurable Embedded System (ARES)

G.5 Army Special Operations

In a presentation to the Association of the US Army, BG Erik Peterson, Commanding General, United States Army Special Operations Aviation Command, indicated that the command has more than 300 unmanned air vehicles.[47] In addition to 12 Gray Eagles, 32 Shadows, 224 Ravens, and 7 Pumas, which are Army Programs of Record (PORs), the command uses other vehicles procured in response to joint urgent operational needs (JUONs) and other requests.

Going forward the Army Special Operations team would like fewer types of UAV with more capability, especially multiple sensors on one UAV. Improved processing, exploitation and dissemination is also needed to fully exploit such multi-sensor capabilities.

G.6 NASA

The NASA Aeronautics Six Strategic Thrusts[48] are shown in Figure G-13. The primary thrust for UAS is the Assured Autonomy for Aviation Transformation. In addition, the Real-Time System-Wide Safety Assurance and the Safe, Efficient Growth in Global Operations Thrusts play a role,

[47] Jen Judson, "Army Special Operations Want Multi-Intelligence UAVs," *Defense News*, 14 January 2016, http://www.defensenews.com/story/defense/land/army-aviation/2016/01/14/army-special-operations-want-multi-intelligence-uavs/78812140/

1034 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

especially for the traffic management systems required for eventual integration of UAS into the civilian airspace. NASA's concept for the unmanned traffic management system is key to

- Safely opening new markets, and
- De-confliction with existing vertical flight.

Figure G-13 NASA Aeronautics Six Strategic Thrusts

In addition to the traffic management systems, NASA has created a design environment for the development of novel vertical lift vehicle platforms including significant focus on UAS as shown in Figure G-14.[49] In light of the capability gap identified by the ASB Study Team, Recommendation 3 - UAS Vehicles, these NASA resources should be leveraged as much as possible.

[49] NASA Aeronautics Research Mission Directorate, *AMRD Briefings to ASB,* 9 June 2015: Susan A. Gorton, "Revolutionary Vertical Lift Technology Project Overview"

1035 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

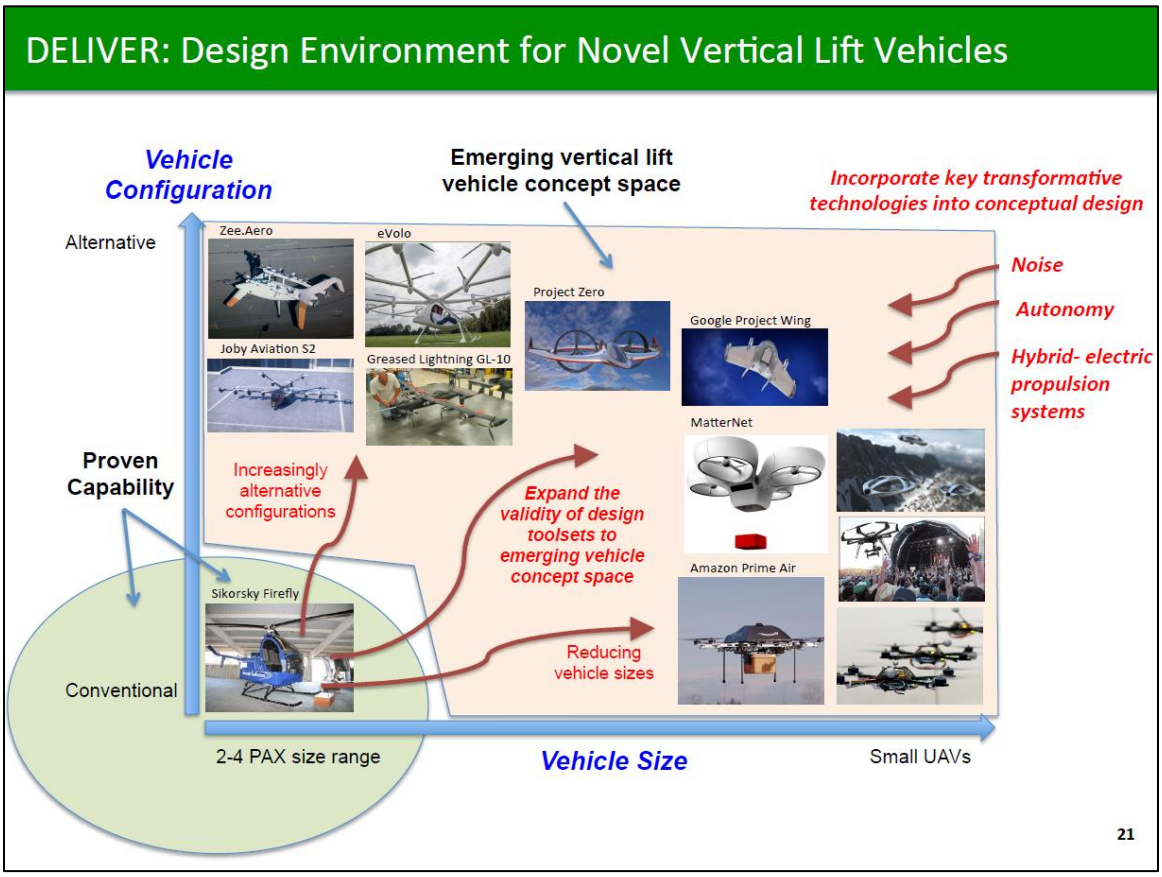

Figure G-14 Design Environment for Novel Vertical Lift Vehicles

G.7 Industry

The US has a healthy UAS industry that spans the gamut from major aircraft companies (i.e., Boeing, Lockheed, Northrop, Sikorsky and Textron) to medium sized companies that specialize in UAS (e.g., General Atomics, Aerovironment, Aurora Flight Sciences) to numerous small innovative companies that provide small UAS, primarily for the commercial market. The investment in UAS and advancement of capabilities through this US-based industrial complex is considerable. However, even with this plethora of activity, the US cannot be assured of asymmetric advantage in UAS systems and capabilities. The rest of the world is also investing in UAS and offer capable systems in the open market. Many of the foreign systems are inexpensive, easy to use, and available to any state or non-state adversary.

APPENDIX H LARGE-SCALE TEST FACILITIES RELEVANT TO ARMY AVIATION

The Army Aviation RDECOM community (AMRDEC and ARL) has established numerous facilities at locations in Virginia and California in support of Army Aviation. Figure H-1 describes the large-scale AMRDEC facilities used for ballistics testing, aerodynamics, countermeasures, large rotor testing, structural testing, and transonic dynamics.

Figure H-1 Key Test Facilities Relevant to Army Aviation

These AMRDEC facilities are unique and provide important capabilities needed to further Army Aviation. These key test facilities, along with other relevant facilities, are described briefly below.

Wind Tunnels:

- National Full-Scale Aerodynamics Complex (NFAC), Moffett Field, CA: Advanced testing of full-scale rotorcraft; 40-by-80 foot wind tunnel circuit is capable of providing test velocities up to 300 knots. The 80-by-120 foot test section is the world's largest wind tunnel and is capable of testing a full-size Boeing 737 at velocities up to 100 knots.
- 7-by-10 foot Wind Tunnel, Moffett Field, CA: Scaled subsonic aerodynamic research.
- Transonic Dynamics Tunnel, Hampton, VA: Helicopter performance loads and stability testing; world's premier wind tunnel for testing large aeroelastically scaled models at transonic speeds.

1037 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Other Major Facilities:

- Ballistics Test Facility, Ft. Eustis, VA: Fuel tank testing up to 30 mm ammunition.
- Countermeasures Test Facility, Ft. Eustis, VA: Acoustic/infrared radiation measurement of turbine engines and suppression devices.
- Structural Test Facility, Ft. Eustis, VA: Rotor-blade root end fixture for loads and fatigue testing; rotor-blade mid-span fixture for loads and fatigue testing; Rotor-Full Scale Dynamics Test Facility.
- Large Rotor Test Apparatus (in NFAC), Moffett Field, CA; Full scale rotorcraft component testing.

Other Key Facilities:

- Rapid Prototyping Facility (RPF), Ft. Eustis, VA: Rapid prototyping of aircraft modifications and developmental test hardware.
- Prototype Integration Facility (PIF), Redstone Arsenal, AL: Multi-discipline facility for fabricating and integrating developmental and operational test hardware and systems for AMRDEC and other customers.
- Advanced Prototype Experimentation (APEX), Redstone Arsenal, AL: Warfighter-in-the-loop simulation facilities for missile, aviation and unmanned systems.
- Aviation System Integration Facility (ASIF), Redstone Arsenal, AL: Avionics & software development integration & testing in a Common Avionics Architecture System (CAAS) and Future Airborne Capability Environment (FACE) based SIL.
- Rotorcraft Aircrew Systems Concepts Airborne Laboratory (RASCAL), Moffett Field, CA: Full-authority variable-stability JUH-60 Black Hawk.
- RASCAL Development Facility, Moffett Field, CA: Ground-based hardware-in-the-loop simulation facility to check out ``experimental'' code before flying on RASCAL.
- RMAX, Moffett Field, CA: two Yamaha RMAX helicopters used for OFN/SLAD autonomy research.

Figure H-2 shows the facilities key to the foundational science work conducted by ARL in the areas of rotorcraft survivability, scientific visualization, materials, robotics, electromagnetics, and propulsion.

APPENDIX I ARMY AVIATION FUNDING

Data in this Appendix is taken from FY16 budget justification documents at http://www.asafm.army.mil/offices/BU/BudgetMat.aspx?OfficeCode=1200 in Sept 2015.

I.1 Army Total Obligation Authority

The President's Budget funding request for FY16 includes $126.4B base funding plus $20.7B overseas contingency operations (OCO) funding. Those funds are distributed across major funding areas as shown in Figure I-1.

FY16 (B$)	Base	OCO	Total
Military Personnel	56.3	2.0	58.3
O&M	44.7	11.5	56.2
Procurement	16.1	1.6	17.7
RDTE	6.9	0.0	6.9
Other	2.4	5.6	8.0
Total	126.4	20.7	147.1

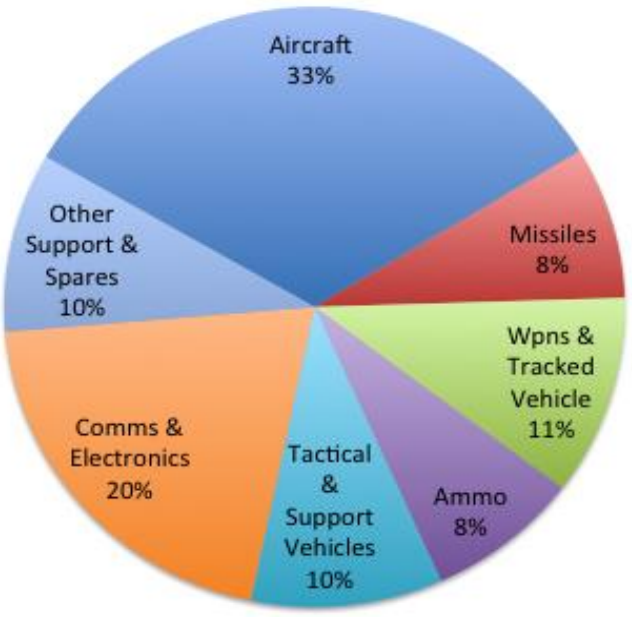

Figure I-1 Distribution of Army TOA Requested for FY16 ($147.1B)

While some of the funding for military personnel and operations & maintenance (O&M) supports Army aviation, the budget documents do not provide sufficient detail to identify those funds separately. The documents do identify procurement funds for aircraft. They also provide sufficient description of RDT&E efforts to estimate aviation funding. Other funding (military construction, family housing, BRAC, Chemical Agents and Munitions Destruction, Army Working Capital Fund, Arlington National Cemetery, and OCO passthrough/transfer) does not appear to directly support aviation.

I.2 Army Procurement Funding

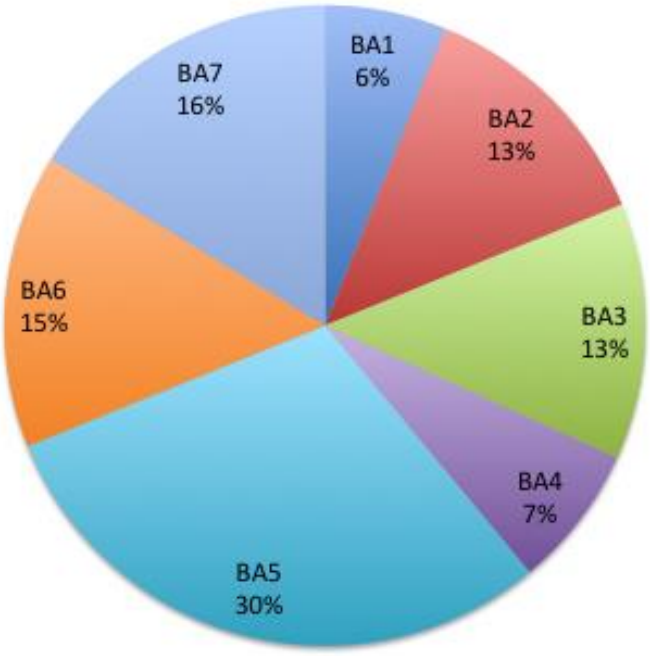
Figure I-2 shows the distribution of Army procurement funding requested for FY16; $5.9B of the $17.8B (33% of the total) is allocated to aircraft systems. This includes funding for purchase of aircraft (fixed wing and rotary wing), modification of aircraft, and support equipment & facilities.

1040 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

FY16 (B$)	Base	OCO	Total
Aircraft	5.7	0.2	5.9
Missiles	1.4	0.0	1.5
Weapons & Tracked Combat Vehicle	1.9	0.0	1.9
Ammunition	1.2	0.2	1.4
Tactical & Support Vehicles	0.8	1.0	1.8
Communication & Electronics	3.5	0.1	3.6
Other Support Equipment & Spares	1.6	0.1	1.7
Total	16.1	1.6	17.8

Figure I-2 Distribution of Army Procurement Funding Requested for FY16 ($17.8B)

I.3 Army RDTE Funding



RDTE funds are allocated in program elements and projects within seven budget activities:

- Budget Activity 1, Basic Research: Systematic study directed toward greater knowledge or understanding of the fundamental aspects of phenomena and of observable facts without specific applications towards processes or products in mind.
- Budget Activity 2, Applied Research: Systematic study to gain knowledge or understanding necessary to determine the means by which a recognized and specific need may be met. It is a systematic application of knowledge toward the production of useful materials, devices, and systems or methods.
- Budget Activity 3, Advanced Technology Development: Includes all efforts that have moved into the development and integration of hardware for field experiments and tests. Projects in this category have a direct relevance to identified military needs.
- Budget Activity 4, Demonstration and Validation. Dem/Val includes all efforts necessary to evaluate integrated technologies in as realistic an operating environment as possible to assess the performance or cost reduction potential of advanced technology.
- Budget Activity 5, Engineering and Manufacturing Development: EMD includes those projects in engineering and manufacturing development for Service use but which have not received approval for full-rate production.
- Budget Activity 6, RDT&E Management Support: Includes R&D effort directed toward support of installations or operations required for general R&D use. Included would be test ranges, military construction, maintenance support of laboratories, O&M of test aircraft and ships, and studies and analyses in support of the R&D program.
- Budget Activity 7, Operational System Development. Includes those development projects in support of development acquisition programs or upgrades still in EMD, but

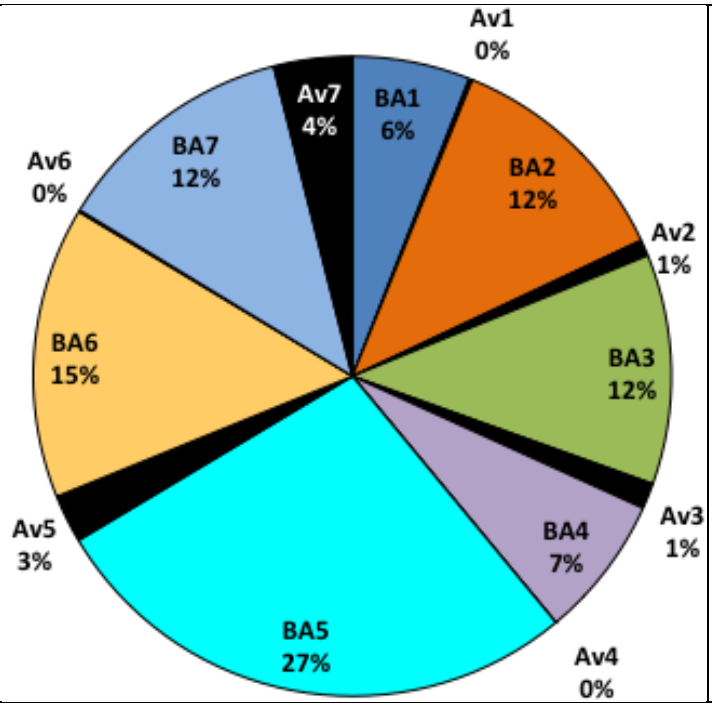
1041 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

which have received Defense Acquisition Board (DAB) or other approval for production, or production funds have been included in the DoD budget submission for the budget or subsequent fiscal year.

Figure I-3 shows the distribution of funds in the FY16 budget request. Only a very small amount of OCO funding is requested for the RDTE accounts.

FY16 (M$)	Base	OCO	Total
BA1	425.1	0.0	425.1
BA2	879.7	0.0	879.7
BA3	895.7	0.0	895.7
BA4	498.7	1.5	500.2
BA5	2,069.0	0.0	2,069.0
BA6	1,027.5	0.0	1,027.5
BA7	1,129.3	0.0	1,129.3
Total	6,925.0	1.5	6,926.5

Figure I-3 Distribution across Budget Activities of RDTE Funding Requested for FY16 ($6.9B)



RDTE budget documents provide sufficiently detailed descriptions to permit estimating the funding allocated to aviation within each budget activity. Figure I-4 shows, for each Budget Activity, the estimated amount of funding supporting Army aviation. The black wedge shown clockwise from each budget activity represents the aviation funding, 8.8% of the Army RDTE total. Note that the aviation RDTE funding totals $609M, slightly more than 1/10 of the aviation Procurement funding.

The largest component of RDTE aviation funding is in BA7, Operational System Development. Over 80% of that funding is allocated to Apache, Blackhawk, and Chinook Product Improvement Programs and the Improved Engine Turbine Program (ITEP).

The next largest component is in BA5, Engineering and Manufacturing Development, with over half of that funding allocated to the Joint Air-to-Ground Missile (JAGM) designed to replace the Hellfire and LONGBOW aviation missiles.

The Science and Technology Budget Activities, BA1-BA3, include $158M for aviation, a little over 7% of the total. These activities are discussed further in the next section.

1042 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

FY16 (M$)	Non-Aviation	Aviation	% Aviation
BA1	413.5	11.6	2.7%
BA2	822.8	56.9	6.5%
BA3	806.0	89.7	10.0%
BA4	500.2	0.0	0.0%
BA5	1,900.0	168.9	8.2%
BA6	1,021.1	6.4	0.6%
BA7	853.9	275.4	24.4%
Total	6,317.5	608.9	8.8%

Figure I-4 RDTE Funds Requested for Aviation

I.4 Army S&T Funding

For Budget Activity 1, Basic Research, budget documents do not provide detailed breakdowns of the planned efforts. Some projects such as the Vertical Lift Research Centers of Excellence clearly support aviation. Others are more general and cannot be linked to specific technologies.

Budget Areas 2, Applied Research, and 3, Advanced Technology Development, support more specific projects that can be linked to aviation or other areas. Approximately 8.3% of Army BA2 and BA3 supports Army aviation. Estimates can also be made of which activities within aviation are supported. Figure I-5 shows estimates for FY16 BA2/3 requests. The largest portion supports the Joint Multi-Role Technology Demonstration. The Degraded Visual Environment (DVE) effort also receives significant support.

Army Science and Technology for Army Aviation 2025-2040

TOR Objective

Identify and assess S&T enhancements capable of being fielded during the **2025-2040** timeframe that will:

- increase Army Aviation's expeditionary capabilities to support full-spectrum military operations, and
- reduce its sustainment tails and logistics footprint.

1046 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

TOR Has Three Tasks

1. **Review** current Army, Navy/USMC, Air Force, DARPA, OSD, NASA and industry aviation S&T **plans, modernization plans and ongoing developments**, as well as relevant Force 2025 and Beyond Campaign activities.
2. Address the use of **innovative technologies** that increase capabilities, overall mission effectiveness, survivability and lethality while reducing sustainment requirements, including logistics footprint and frequency of resupply.
   Include, but not necessarily be limited to, the following key focus areas for improvement:
   - near-zero maintenance platforms and systems,
   - exploitation of unmanned aircraft systems,
   - meeting the challenges of emerging threats,
   - enhancing the ability to operate worldwide in a variety of stressing and degraded visual conditions.
3. Determine the **feasibility and risks** associated with each of the findings and recommendations.

FM 525-3-1 Army Operational Concept: Win In A Complex World

- Respond Globally: "When called upon, globally responsive combined arms teams ***maneuver from multiple locations*** and domains to present multiple dilemmas to the enemy..."
- Conduct Joint Combined Arms Operations: "Joint combined arms operations create multiple dilemmas for the enemy. Army forces ***achieve surprise*** through ***maneuver across strategic distances*** and arrival at unexpected locations. Army forces have the mobility, protection and firepower necessary to strike the enemy from unexpected directions. In high ***anti-access and area denial*** environments, ***dispersion*** allows future army forces to evade enemy attacks, deceive the enemy and achieve surprise."
- Sustain High Tempo Operations: "Army sustainment units integrate efforts with Joint Force to ensure unimpeded sustainment flows across land, air and maritime domains. These units provide supplies and services to the ***point of need...***"

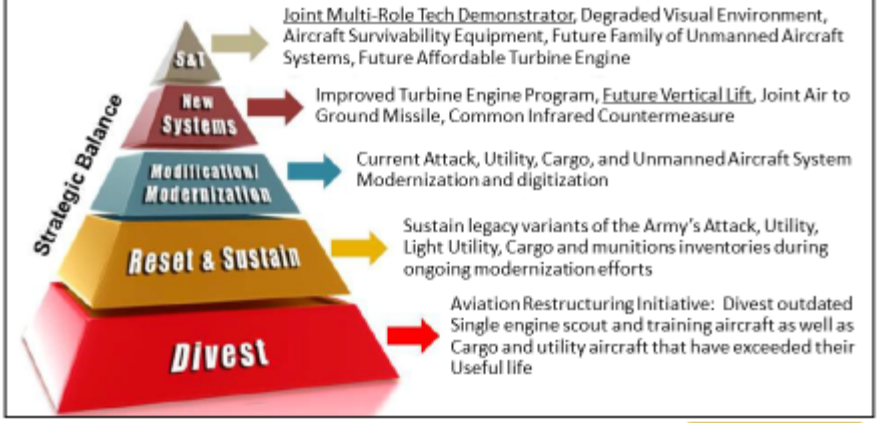
Operational maneuver and sustainment to point of need of dispersed forces

Army Science Board 11

Complex Threats and Opportunities

Army Science Board 12

1050 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING



Unified Quest 2014 Conclusions

- "Self-deployable Army future **vertical lift** capabilities and joint shallow draft systems must be capability development options. These capabilities are **essential** to future strategic, operational, and tactical maneuver and enable dispersed forces to maintain mutually supportive functions."
- **"Unmanned** air and ground platforms that enhance soldier decision-making and action with self-planning, self-navigation, and mission execution capabilities will have significant potential to change the future battlefield. The Army must develop concepts of employment for future autonomous and unmanned systems in the near-term to integrate them efficiently into the force in the far-term (2030-2040)."

Army Science Board 13

Army Aviation Modernization Strategy

Invest in essential technologies that have a high likelihood of successful transition to Affordable programs, to help close capability gaps in a resource constrained environment. Incrementally upgrade Aviation platforms, divest old systems and invest in new platforms and technologies, in order to maintain modernized aircraft that can defeat **new and increasingly complex threats.**

Army Science Board 14

1051 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

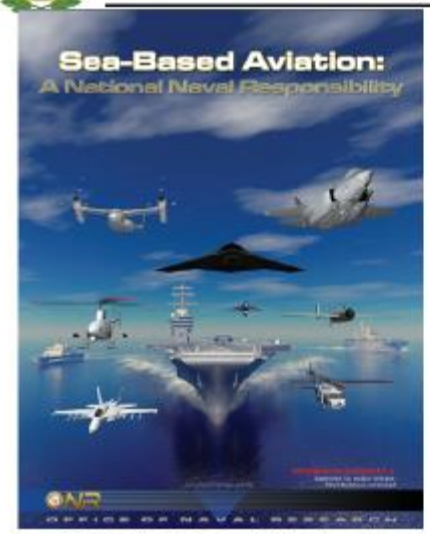
Joint Multi-Role Tech Demo (JMR-TD)

- JMR-TD is cost sharing effort between Army and Vendors. Four vendors selected Oct 2013 to begin design for vehicle demonstrator:
  - AVX – coaxial-rotor, ducted-fan compound helicopter
  - Bell – tilt rotor
  - Karem - variable-speed tilt rotor
  - Sikorsky Boeing – coaxial rigid-rotor, pusher-propulsor design

- Down-selected Aug 2014 to Bell "V-280 Valor" and Sikorsky-Boeing "Defiant" to build demonstrators for 2017 flight. AVX and Karem funded for tech development.
- Both JMR TD variants use existing engines (Bell – CH-53, Sikorsky – CH-47)

Army Science Board 15

Future Vertical Lift Family of Systems



- FVL FoS is a Joint **initiative**, not yet a **program**, to develop a 5-class family of rotorcraft for DoD (light, medium, heavy).
- Although requirements are still being refined, the notional concept for a new aircraft must:*
  - reach speeds of 230 knots
  - carry up to 12 troops
  - Operate in "high-hot" conditions at altitudes of 6,000 ft and temperatures of 95-degrees Fahrenheit,
  - have a combat radius of 263 mi with an overall unrefueled range of 527 mi
  - have optionally piloted or supervised autonomous flight capabilities
- Mission sets include: cargo; utility; armed scout; attack; humanitarian assistance; medical evacuation; anti-submarine warfare; anti-surface warfare; land/sea search and rescue; special warfare support; vertical replenishment; airborne mine countermeasures.

1052 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Navy and Air Force Have Visions for UAS

SECNAV: "F-35C should be Navy's last manned strike jet" 4/16/15

General Impressions Gained From Review

- **Army manned aviation S&T:** Generally well balanced (e.g. JMR-TD & FVL)
- **Outside investments:** NASA, USAF, USN/USMC, DARPA and industry have promising innovative technology and concepts that could be leveraged
- **Survivability**: Sophisticated threats place Army aviation assets at high risk. These threat capabilities are growing and proliferating.
- **Architecture**: Survivability against 2025+ threats will require system of systems (SoS) solutions that exploit the power of collaborative manned-unmanned teaming (MUM-T). The operational and system architectures and CONOPS for these SoS solutions have not been defined.
- **Unmanned Systems**: Army aviation requires a strong vision for the expanded use of UAS. Currently, there is neither the vision nor the funding to exploit the potential of UAS, autonomy and MUM-T
- **Manned Systems**: Legacy manned systems are 1970 vintage designs. Next generation systems (FVL) are scheduled for IOC in mid 2030s.
- **Maneuver**: Army CONOPS requires expeditionary and operational maneuver of dispersed mechanized forces. Army aviation assets cannot satisfy this need.
- **Army Aviation RDT&E Budget**: Inadequate to meet future aviation challenges. FVL is not funded; industrial base is eroding.

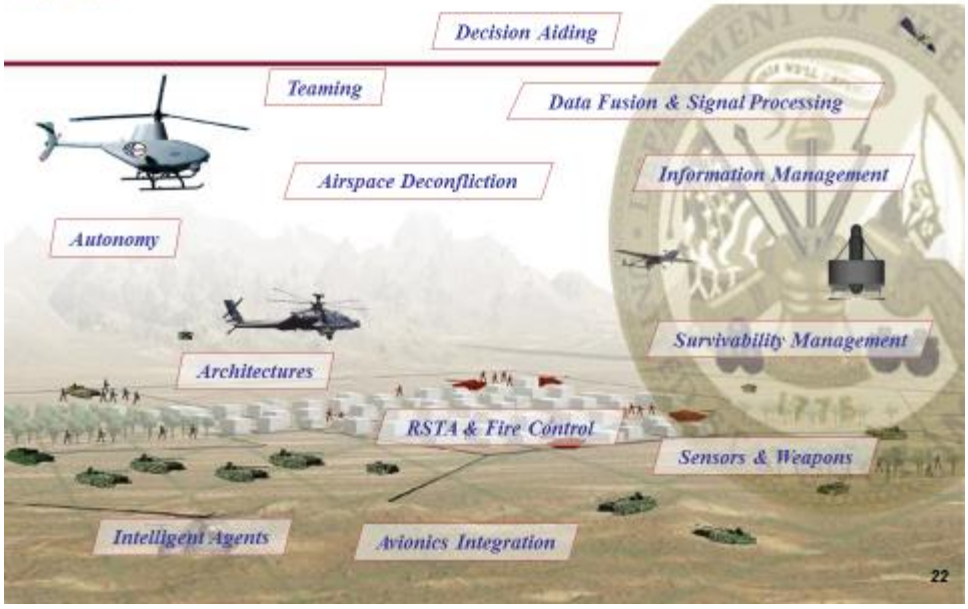
9. S&T Investment Strategy

Army Science Board 20

1054 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

1. System of Systems Operational Effectiveness Analyses

Findings



- Increasing threat sophistication and proliferation (e.g., missiles, UAS, cyber, and directed energy) pose critical concerns. (Classified annex provides additional details)
- Platform-centric survivability must evolve to a manned-unmanned system-centric approach with new CONOPS and TTPs.
- A system of systems architecture should include manned-unmanned teaming, supervised autonomous systems, and secure communications.

Recommendation

- TRADOC: Conduct operational effectiveness analyses of potential system of systems concepts in a cost-constrained environment that address capability gaps for Army aviation in 2025 and beyond in complex threat environments. Concepts should include holistic air-ground approaches, high/low mixes of collaborative manned/unmanned systems, FVL performance characteristics, higher levels of autonomy, PNT in denied GPS environments, attritable UAS assets and enhanced lethality of DE. Develop CONOPS and architectures for the most cost effective concepts.

Army Science Board 21

Integrated Battlespace

1055 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

2. Affordability of Heavy Vertical Lift (HVL)

Findings

- Heavy vertical lift (20-30 stons) is required by the Army CONOPS for expeditionary and operational maneuver, validated by JROC (documented in the FVL and JHL ICDs) and supported by Unified Quest 2014, and "2012 Gaining and Maintaining Access: An Army-Marine Corps Concept."
- However, development of a new system is cost prohibitive within likely future Army modernization (RDA) funding before 2040.
- Interim solutions able to provide more limited capability are available (e.g., CH-53K at 18 stons, and Joint Precision Air Drop System – JPADS) and could provide viable options.

Recommendation

- TRADOC: Assess interim and future HVL options for meeting Army CONOPS and documented JCIDS capability needs for expeditionary and operational maneuver and recommend road ahead
  - If development of HVL is cost prohibitive, consider alternatives.
  - If there are no plans for HVL, do not assume it is available in analyses, wargames, and exercises.

Army Science Board 23

Historical Heavy Vertical Lift Options

Army Science Board 24

1056 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Findings & Recommendations Overview

Context: Character of Warfare in 2025 and Role of Army Aviation

1. System of Systems Operational Effectiveness Analyses
2. Affordability of Heavy Vertical Lift

Addressing Capability Gaps: Development and Acquisition

3. UAS Vehicles
4. Modernization of Legacy Rotorcraft Systems
5. FVL Acquisition with Speed and Simplicity
6. Aviation Mission Systems
7. Aviation Systems Integration and Testbed

S&T Portfolio: Innovation and Game Changers

8. Advanced and Disruptive Systems S&T
9. S&T Investment Strategy

3. UAS Vehicles

Findings

- The USN/USMC and USAF have strong visions for the expanding role of UAS and manned-unmanned teaming in aviation missions.
- DARPA, USN/USMC and USAF are investing in next generation UAS technology options that offer potential capability for Army aviation.
- New UAS are needed to fully exploit manned–unmanned synergy and collaboration of manned systems with supervised autonomous systems within a system-of-systems architecture.

Recommendation

- ASA(ALT): Revise UAS Roadmap to expand near-term and future UAS vehicle options, some of which should be compatible with speed, hover, and range of current and future manned aircraft, with attributes compatible with distributed functionality among UAS (ISR, Lethality, …) as informed by the results of system of systems operational effectiveness analyses (Recommendation 1)

1057 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

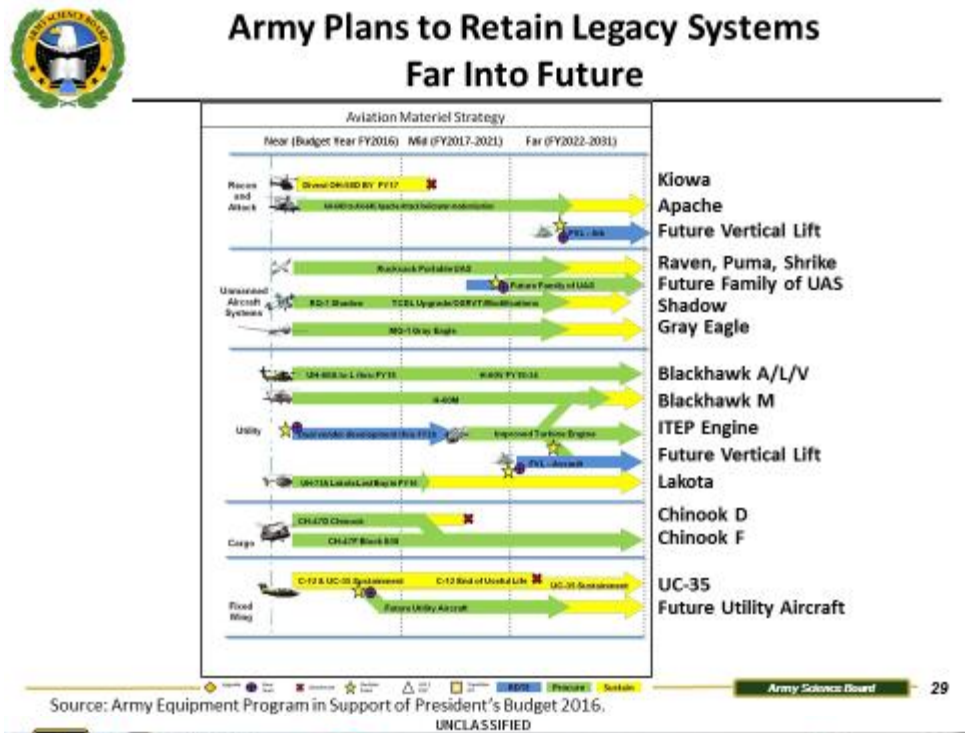
Distributed Functionality Collaborative System of Systems Concept

Low End Single Function Unmanned Systems
Complement and Expand Capability of High End System

Army Science Board 27

4. Modernization of Legacy Rotorcraft Systems

Findings



- Legacy rotorcraft systems (AH-64, CH-47 and UH-60) are expected to remain deployed until at least 2060, requiring modernization investment.
- Within the current limited budget, Army aviation S&T is investing in technologies that apply to both legacy and future manned systems.
- These technologies include: ITEP/FATE engine insertion, DVE capabilities, CBM/PHM capabilities, ASE improvements, and greater MUM-T.

Recommendation

- ASA(ALT): Continue S&T and road-mapping efforts for modernizing legacy systems with emphasis on those technologies that are also applicable to future vehicles, as informed by the results of system of systems operational effectiveness analysis (Recommendation 1).

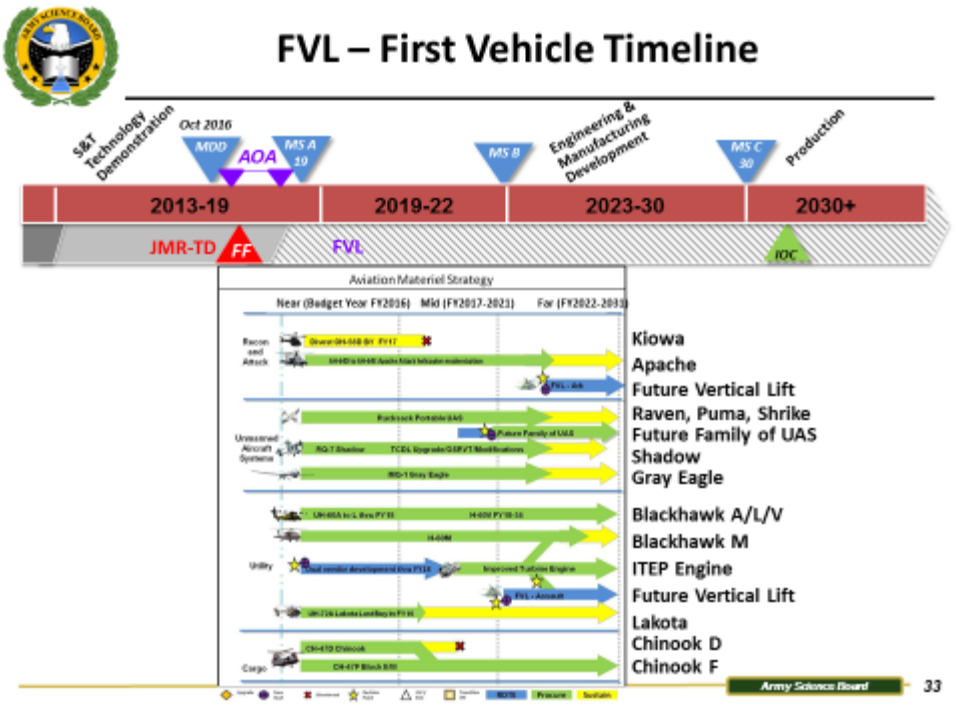
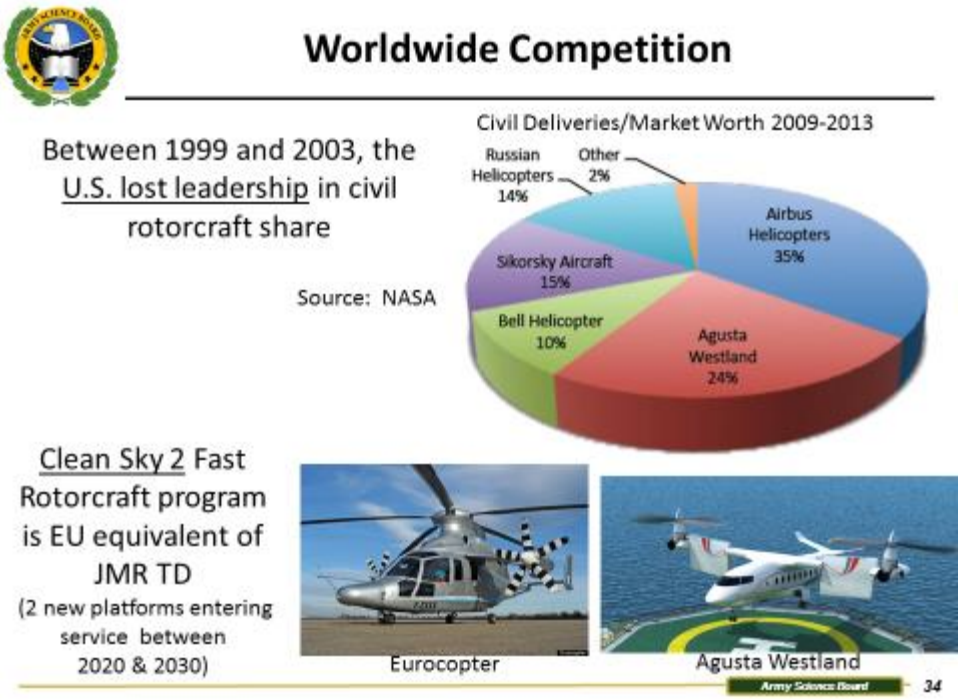
ITEP Provides Significant Improvement in Performance of Legacy Platforms

5. FVL Acquisition with Speed and Simplicity



Findings



- JMR-TD and FVL provide focus for Army Aviation S&T for next generation rotorcraft systems and provide a solid basis for much needed capability improvements (Ref. FVL ICD); however, there is no funding for FVL in the POM.
- The JMR-TD vehicles are close in size and aerodynamic performance capability to the FVL medium class system.
- The current FVL schedule leads to an IOC of the first system in the mid 2030s. It should be beneficial to accelerate this timeline through an evolutionary acquisition approach if funding allows.
- The JMR-TD, DARPA X planes, USN/USMC prototyping efforts, and industry investment support talent development and retention in rotorcraft government and industry teams.

Recommendation

- ASA(ALT): Develop an evolutionary acquisition approach for FVL to allow for earliest possible fielding consistent with funding constraints, as informed by the results of system of systems operational effectiveness analyses (Recommendation 1).

1060 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

1061 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

6. Aviation Mission Systems

Findings

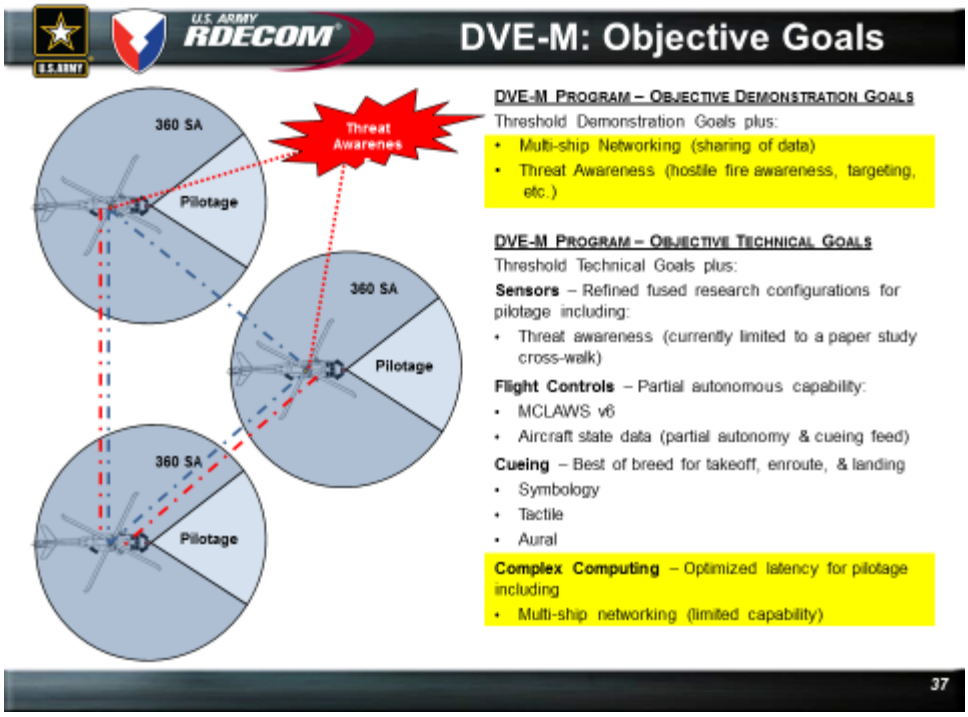
- Army S&T mission system programs include Lethality, Survivability, Teaming & Autonomy, Human-System Interface, Avionics, and Networks.
- RDECOM DVE goals are appropriate and feasible - Progress at AMRDEC, CERDEC, and ARL in sensors, flight control, cueing, computing, and networking.
- Reduced pilot workload arising from DVE technologies should increase operational mission capacity (e.g., formations with UAS).
- Advanced sensors (e.g., IR, visible, and hyperspectral) are being developed.
- Additional advanced mission systems (e.g., offensive and defensive directed energy) and open system architectures are needed.
- DoD provides singular modeling and wind tunnel capabilities (NASA Ames)

Recommendation

- AMRDEC/ADD: Expand mission system technology development, currently focused on DVE, to enable advanced formation concepts in future manned and unmanned platforms, and legacy platforms as appropriate, as informed by the results of system of systems operational effectiveness analyses (Recommendation 1).

Army Science Board 35

The DVE Environments: 2 + 9



TRADOC DVE Definition (2011) – Reduced visibility of potentially varying degree, wherein situational awareness and aircraft control cannot be maintained as comprehensively as they are in normal visual meteorological conditions and can potentially be lost.

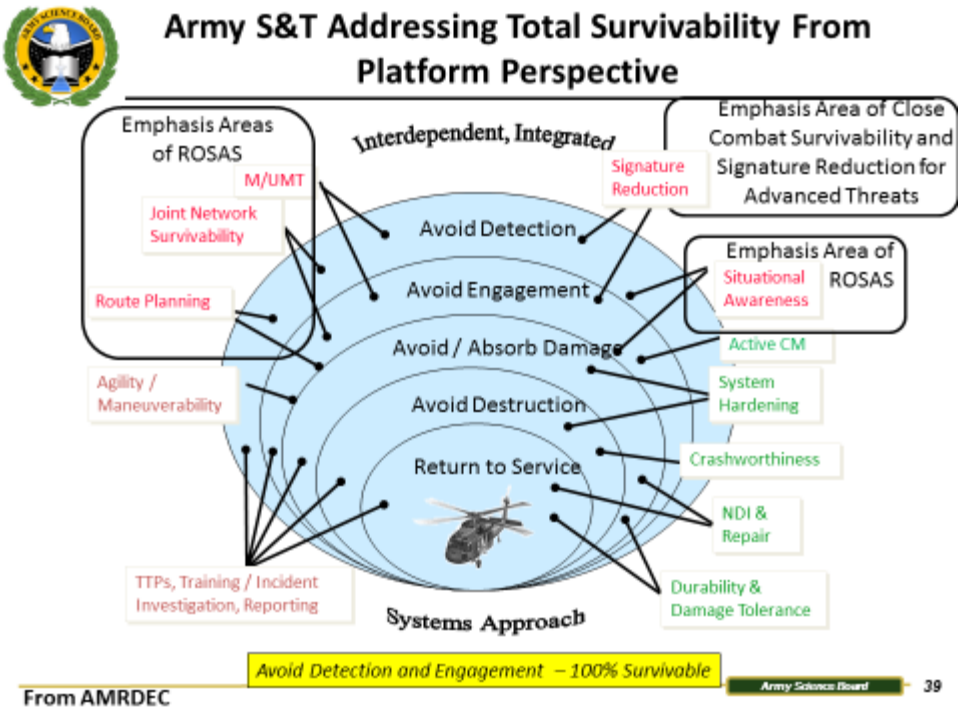
In the 1980's, IR technology allowed the US military to claim "We own the night!" . . . The RDECOM Rotorcraft DVE Mitigation Program overall goal is to "OWN THE WEATHER!".

36

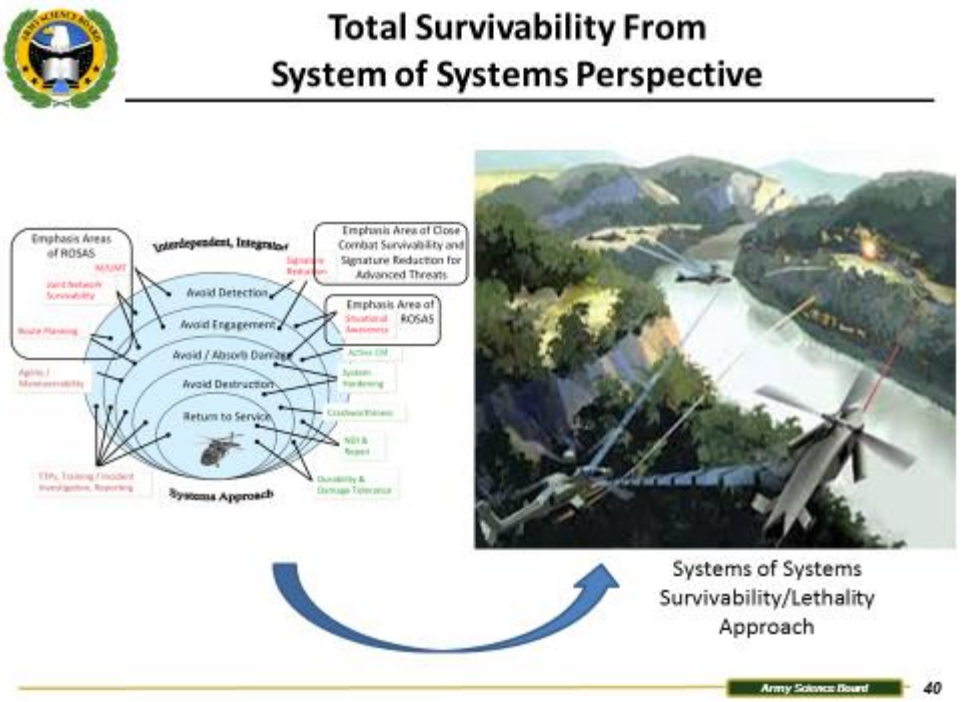
1062 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

7. Aviation Systems Integration and Testbed

Findings



- Concepts developed in Recommendation 1 and new technical capabilities referenced in Sections 2-6 (individually and as integrated systems) will require extensive testing.
- Some initial work is found in CERDEC I2WD open systems efforts and DARPA's System of Systems Integration, Technology and Experimentation (SoSITE).
- Fully integrated joint vision for aviation in DoD is not evident. Coalition environment should be considered.



Recommendations

- RDECOM: Build the components of an integrated "survivable" system (MUM-T, attritable assets, secure comm, PNT, open operating systems, autonomy, high/low mix, distributed functions across future "formations").
- RDECOM: Building on Recommendation 1 and Sections 2-6, develop an aviation integration testbed for experimentation and validation of technology, prototypes, and concepts. Potentially include demonstration (such as JMR TD), prototype, surrogate, and operational systems.

Findings & Recommendations Overview

Context: Character of Warfare in 2025 and Role of Army Aviation

1. System of Systems Operational Effectiveness Analyses
2. Affordability of Heavy Vertical Lift

Addressing Capability Gaps: Development and Acquisition

3. UAS Vehicles
4. Modernization of Legacy Rotorcraft Systems
5. FVL Acquisition with Speed and Simplicity
6. Aviation Mission Systems
7. Aviation Systems Integration and Testbed

S&T Portfolio: Innovation and Game Changers

8. Advanced and Disruptive Systems S&T
9. S&T Investment Strategy

Army Science Board 42

1065 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

8. Advanced and Disruptive Systems S&T

Findings

- Army aviation is at a crossroad of challenge and opportunity.
  - The challenge: threat sophistication will demand a transformation in the nature of warfare in 2025 and beyond (missiles, UAS, DE, Cyber).
  - The opportunity: technology is emerging that enables significant improvement in aviation capabilities.
- Advanced technology solutions are required, including: UAS, autonomy, manned-unmanned collaboration, communications, directed energy, sensors, condition-based and near-zero maintenance technology/concepts, and other discoveries from the S&T enterprise.
- There is relevant work in other Services, DARPA, and NASA that should be leveraged.

Recommendations

- RDECOM: To address expanding complex threats and opportunities develop advanced technologies for an integrated/holistic, manned/unmanned architecture/system to ensure survivability and mission success.
- ASA(ALT): Include in S&T portfolio leap-ahead technologies (counter-DE, counter-UAS, advanced materials)

Army Science Board 43

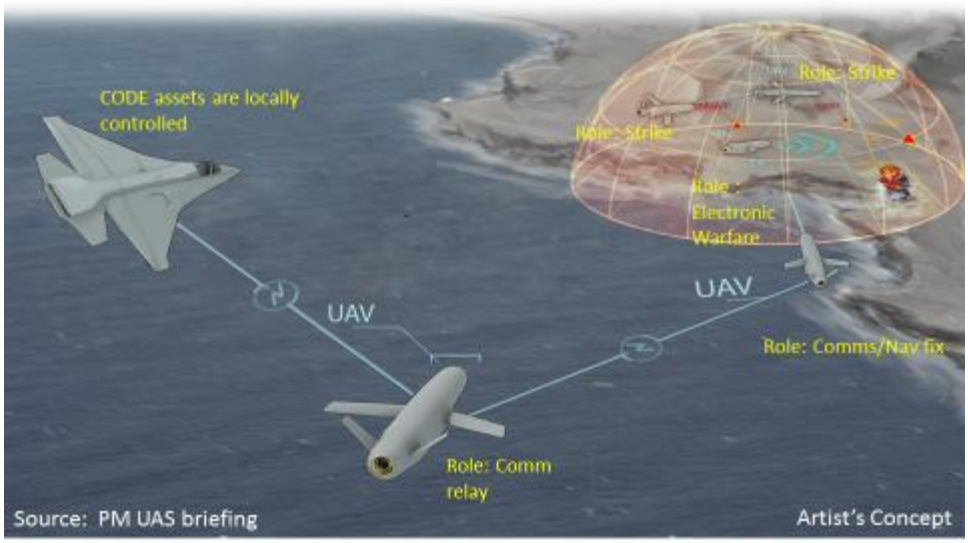
Aviation Innovation Examples

DARPA X-Plane

ARES (DARPA)

Great Horned Owl (Air Force)

Air Launch UAVs (Boeing)



Army Science Board 44

1066 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Collaborative Operations in Denied Environment (CODE)

45

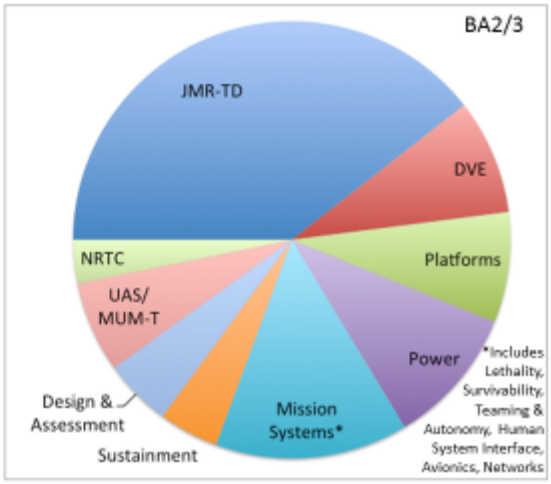
9. S&T Investment

Findings

- Based on findings in Sections 1-8, the capabilities of Army Aviation S&T must evolve rapidly (e.g., need to expand UAS and autonomy activity); thus the level of S&T activity must expand beyond the manned aviation S&T portfolio, which is currently well managed.
- Army S&T investment has led to successful ITEP and FATE engine developments; the transition of these S&T efforts to PORs is essential to both FVL and modernized legacy platforms.
- Current S&T investment is insufficient to achieve the needed transformation and to maintain overmatch in 2025 and beyond.

Recommendations

- AMRDEC/ADD: Continue active participation in VAATE and RAMPED engine development.
- RDECOM: Explore innovative mechanisms for external collaboration (university, industry, etc.), such as grand challenges (similar to DARPA construct).
- ASA(ALT): After exploring leveraging opportunities with other R&D activities, advocate more funding for Aviation S&T.



Army Science Board 46

1067 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Meeting Future Challenges Demands a Robust Aviation Portfolio

- Army FY16 Requested TOA is $126B
- Procurement Total is $16.1B
- Aviation Procurement is $5.7B (34% of Procurement)
- Army S&T* Total is $1.77B
- Army Aviation S&T* is $144M (8% of S&T)
- DoD Rotorcraft S&T* is $207M (Army is lead Service with 64% of total)
- NASA Rotorcraft Funding is $20M

*BA2/3

Current level and focus of funding is inadequate to meet challenges

Army Science Board 47

Findings & Recommendations Summary

Context: Character of Warfare in 2025 and Role of Army Aviation

1. System of Systems Operational Effectiveness Analyses
2. Affordability of Heavy Vertical Lift

Addressing Capability Gaps: Development and Acquisition

3. UAS Vehicles
4. Modernization of Legacy Rotorcraft Systems
5. FVL Acquisition with Speed and Simplicity
6. Aviation Mission Systems

1068 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Future of Army Aviation

Threats are rapidly changing

Character of warfare is changing

Army aviation must change too

Need new **concepts** - beyond stand-alone platforms

New joint battlespace system-of-systems architecture/CONOPS

New systems – UAS, FVL, autonomy, missions systems

New prototyping, experimentation, and testbed

Increase **innovation** and risk-taking to leap ahead/anticipate

Survive and Win as an Aviation System of Systems

1069 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

APPENDIX K ABBREVIATIONS AND ACRONYMS

A2	Anti-Access
AATD	Aviation Applied Technological Directorate – merged with AFDD to form ADD – Ft Eustis, VA
ACAT I	Acquisition Category I (Major Defense Acquisition Programs)
AD	Area Denial
ADD	Aviation Development Directorate in AMRDEC – Merger of AATD and AFDD
AFDD	Aeroflight Dynamics Directorate – merged with AATD to form ADD – Moffett Field, CA
AFOSR	Air Force Office of Scientific Research – Arlington, VA (see also ARO and ONR)
AFRL	Air Force Research Laboratory (see also ARL and NRL)
AH	Attack Helicopter
AIPT	Acquisition IPT (FVL – Army PEO Aviation lead)
AMCOM	Aviation and Missile Command
AMRDEC	Aviation and Missile RDEC – Redstone Arsenal, Huntsville, AL
AO	Area of Operations
AoA	Analysis of Alternatives
APG	Aberdeen Proving Ground, MD
ARCIC	Army Capabilities Integration Center – subordinate to TRADOC
ARDEC	Armament RDEC – Picatinny Arsenal, NJ
ARES	Aerial Reconfigurable Embedded System (DARPA effort)
ARI	Aviation Restructuring Initiative proposed by Army
ARL	Army Research Laboratory – Adelphi, MD and APG, MD (see also AFRL and NRL)
ARO	Army Research Office, part of ARL – Raleigh-Durham, NC – Oversees external efforts in BA1 (see also AFOSR and ONR)
AS	Aviation Systems – a PM in PEO Aviation
ASA(ALT)	Assistant Secretary of the Army (Acquisition, Logistics, and Technology)
ASB	Army Science Board
ASD(R&E)	Assistant Secretary of Defense (Research & Engineering)
ASE	Aircraft Survivability Equipment
ASH	Armed Scout Helicopter – a PM in PEO Aviation
ASSP	Aviation S&T Strategic Plan (produced by ADD)
ASW	Anti-submarine Warfare
AUSA	Association of the US Army
BA1	Budget Activity 1 (DoD), Basic Research - directed toward increasing fundamental knowledge and understanding in those fields of the physical, engineering, environmental, and life sciences related to long-term national security needs. Also called 6.1
BA2	Budget Activity 2 (DoD), Applied Research - systematic expansion and application of knowledge to develop useful materials, devices, and systems or methods. Also called 6.2
BA3	Budget Activity 3 (DoD), Advanced Technology Development (ATD) - development of subsystems and components and efforts to integrate subsystems and components

1070 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

	into system prototypes for field experiments and/or tests in a simulated environment. Also called 6.3
BA4	Budget Activity 4 (DoD): Demonstration and Validation - Dem/Val includes all efforts necessary to evaluate integrated technologies in as realistic an operating environment as possible to assess the performance or cost reduction potential of advanced technology.
BA5	Budget Activity 5 (DoD): Engineering and Manufacturing Development - EMD includes those projects in engineering and manufacturing development for Service use but which have not received approval for full-rate production..
BA6	Budget Activity 6 (DoD): RDT&E Management Support - Includes R&D effort directed toward support of installations or operations required for general R&D use. Included would be test ranges, military construction, maintenance support of laboratories, O&M of test aircraft and ships, and studies and analyses in support of the R&D program.
BA7	Budget Activity 7 (DoD): Operational Systems Development. - Includes those development projects in support of development acquisition programs or upgrades still in EMD, but which have received Defense Acquisition Board (DAB) or other approval for production, or production funds have been included in the DoD budget submission for the budget or subsequent fiscal year.
BDA	Battle Damage Assessment
BRAC	Base Realignment and Closure
C2	Command and Control
C4ISR	Command, Control, Communications, Computers, Intelligence, Surveillance and Reconnaissance
CAPE	Cost Assessment and Program Evaluation (OSD)
CAS	Close Air Support
CBA	Cost-Benefit Analysis or Capabilities Based Assessment (part of JCIDs process)
CBM	Condition Based Maintenance
CCA	Close Combat Attack
CCS	Close Combat Survivability
CERDEC	Communications-Electronics RDEC – APG, MD
CG	Commanding General
CH	Cargo Helicopter
CIPT	Commonality IPT (FVL – Navy PEO Assault and ASW lead)
CM	Countermeasure
CODE	Collaborative Operations in Denied Environment (DARPA effort)
COE	Center of Excellence
COI	Community of Interest
CONOP	Concept of Operations
CONUS	Continental US
CSA	Chief of Staff of the Army
CSAR	Combat Search and Rescue
DA	Direct Attack
DAB	Defense Acquisition Board

1071 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

DARPA	Defense Advanced Research Projects Agency
DE	Directed Energy (includes high energy laser and high powered microwave)
DHS	Department of Homeland Security
DoD	Department of Defense
DSB	Defense Science Board
DTIC	Defense Technical Information Center (www.dtic.mil)
DVE	Degraded Visual Environment (includes brownouts, whiteouts, rain, snow, fog, sleet, mist, etc.)
DVE-M	DVE - Mitigation
ECBC	Edgewood Chemical and Biological Center – Edgewood, MD
EMD	Engineering and Manufacturing Development
EMI	Electromagnetic Interference
EO	Electro-Optic
ESD	Electrostatic Discharge
EW	Electronic Warfare
FA	Focus Area (at ADD)
FACE	Future Airborne Capability Environment
FATE	Future Affordable Turbine Engine
FCS	Future Combat System
FoS	Family of Systems
FOUO	For Official Use Only
FVL	Future Vertical Lift
FW	Fixed Wing – a PM in PEO Aviation
FY	Fiscal Year
GCS	Ground Control System
GMTI	Ground Moving Target Indicator
GPS	Global Positioning System
HA/DR	Human Assistance/Disaster Relief
HOGE	Hover Out of Ground Effect
HQDA	Headquarters Department of the Army
HSL	Helicopter Sling Load
HUMS	Health and Usage Monitoring System
HVL	Heavy Vertical Lift
I2WD	Intelligence and Information Warfare Directorate of CERDEC – APG, MD
ICD	Initial Capabilities Document
IED	Improvised Explosive Device
IEW&S	Intelligence, Electronic Warfare & Sensors
IHSMS	Integrated Hybrid Structures Management System (Navy)
ILIR	In-House Laboratory Innovative Research (BA1)
IOC	Initial Operational Capability
IPT	Integrated Product Team
IR	Infrared
ISR	Intelligence, Surveillance, and Reconnaissance
ITEP	Improved Turbine Engine Program

1072 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

IVSHM	Integrated Vehicle Self Health Monitoring
JAGM	Joint Air-to-Ground Missile
JCA	Joint Common Architecture
JCIDS	Joint Capabilities Integration and Development System, the formal United States DoD procedure that defines acquisition requirements and evaluation criteria for future defense programs
JF	Joint Force
JFTL	Joint Future Theater Lift – concept to lift 20-36 tons – USAF lead JFTL definition 2008-2012, canceled 2012
JFVL	Joint Future Vertical Lift
JHL	joint Heavy Lift – Army exploration of large tilt-rotor concept to lift ~30 tons over theater distances
JLTV	Joint Light Tactical Vehicle
JMR	Joint Multi-Role
JROC	Joint Requirements Oversight Council
kt	knot (1 nautical mile per hour = 1.852 km per hour)
LCC	Life Cycle Cost
LGB	Laser-Guided Bomb
LIRA	Long-Range Investment Requirements Analysis
M&S	Modeling & Simulation
MANPADS	Man-Portable Air Defense System
MCLAWS	Modernized Control Laws
MDD	Materiel Development Decision
MEDEVAC	Medical Evacuation
MEP	Mission Equipment Package
MFOP	Maintenance Free Operating Period
MSA	Milestone A – decision to move from Materiel Solution Analysis to Technology Development
MSB	Milestone B – decision to move from Technology Development to Engineering and Manufacturing Development
MSC	Milestone C – decision to move from Engineering and Manufacturing Development to Production and Deployment
MUM-T	Manned Unmanned Teaming
NASA	National Aeronautics and Space Administration
NAVAIR	Naval Air Systems Command
NDI	Non-Developmental Item
NDIA	National Defense Industrial Association
NEO	Noncombatant Evacuation Operations
NM	Nautical mile
NRL	Naval Research Laboratory – Washington, DC (see also AFRL and ARL)
NRTC	National Rotorcraft Technology Center at NASA Ames – an interagency team of NASA, Army, Navy, and FAA – focuses government, industry, and academic resources
NSRDEC	Natick Soldier RDEC - Natick MA

1073 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

NSRWA	Non-Standard Rotary Wing Aircraft – a PM in PEO Aviation
NVESD	Night Vision and Electronic Sensor Directorate of CERDEC – Ft. Belvoir, VA
O&M	Operations and Maintenance
O&S	Operations and Support
OCO	Overseas Contingency Operations
OEF	Operation Enduring Freedom
OMS	Open Mission Systems (USAF effort)
ONR	Office of Naval Research – Arlington, VA (see also AFOSR and ARO)
OSA	Open Systems Architecture
OSD	Office of the Secretary of Defense
OT&E	Operational Test and Evaluation
P3I	Pre-Planned Product Improvement
Pax	Passengers
PEO	Program Executive Office, e.g. PEO-Aviation at Redstone Arsenal, AL
PHM	Prognostic Health Management
PM	Program Manager in PEO, e.g., in PEO Aviation PMs are Apache, AS, ASH, Cargo, NSRWA, UH, UAS, FW
PNT	Positioning, Navigation and Timing
POD	Point of Departure or Point of Debarkation
POM	Program Objective Memorandum
POR	Program of Record – Acquisition program that has achieved MSB
R&D	Research and Development
RDA	Research Development and Acquisition
RDEC	Research, Development, and Engineering Center
RDECOM	Research, Development, and Engineering Command – RDECOM Organizations include ARDEC, AMRDEC, CERDEC, ECBC, NSRDEC, TARDEC and ARL – APG, MD
RDTE	Research Development Test & Evaluation (RDT&E funding includes BA1-BA7 budget areas)
RF	Radio Frequency
RIPT	Requirements IPT (FVL – TCM-Lift lead))
ROSAS	Route Optimization for Survivability Against Sensors (Army effort)
RSOI	Reception, Staging, Onward movement, and Integration
RSTA	Reconnaissance, Surveillance, and Target Acquisition
RVLT	Revolutionary Vertical Lift Technology (NASA project)
RW	Rotary Wing – a PM in PEO Aviation
S&T	Science & Technology – within DoD funded by BA1, BA2, and BA3
SA	Situational Awareness
SAM	Surface to Air Missile
SAR	Synthetic Aperture Radar
SBIR	Small Business Innovative Research
SEAD	Suppression of Enemy Air Defense
SIGINT	Signals Intelligence
SIL	Software Integration Laboratory
SLAD	Survivability/Lethality Analysis Directorate (ARL)

1074 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

SOCOM	Special Operations Command
SOF	Special Operations Force
SOIPT	S&T Overarching IPT (FVL – AMRDEC lead)
SoS	System of Systems
SoSITE	System of Systems Integration technology and Experimentation (DARPA effort)
SRAT	Signature Reduction Against Threats
STOL	Short Take-Off and Landing
SuW	Surface Warfare (Navy)
SWAP	Size, Weight, and Power
TA	Technical Area (at ADD)
TARDEC	Tank Automotive RDEC – Warren, MI
TCM	TRADOC Capability Manager
TD	Technology Demonstration
TOA	Total Obligation Authority
TOR	Terms of Reference
TRADOC	US Army Training and Doctrine Command – Ft Eustis, VA
TTO	Tactical Technology Office (DARPA)
TTP	Tactics, Techniques, and Procedures
UAS	Unmanned Aircraft System
UAV	Unmanned Aerial Vehicle
UH	Utility Helicopter – a PM in PEO Aviation
UNK	Unknown
UQ	Unified Quest (Army chief of staff annual future studies program, includes wargame)
USA	US Army
USAACE	US Army Aviation Center of Excellence – Ft. Rucker, AL
USAARL	US Army Aeromedical Research Laboratory – Ft. Rucker, AL
USAF	US Air Force
USCG	US Coast Guard
USMA	US Military Academy at West Point
USMC	US Marine Corps
USN	US Navy
V/STOL	Vertical/Short Take-Off and Landing
VAATE	Versatile Affordable Advanced Turbine Engine
VCSA	Vice Chief of Staff of the Army
VLC	Vertical Lift Consortium (Industry)
VLRCOE	Vertical Lift Research Center of Excellence (at Georgia Tech, Penn State, and U Md) – Funded with BA1
VRAMS	Virtual Risk-informed Agile Maneuver Sustainment
VTOL	Vertical Take-Off and Landing
WIPT	Working IPT under SOIPT (FVL)
WMD	Weapons of Mass Destruction
ZMA	Zero Maintenance Aircraft

13. ABSTRACT (maximum 200 words)

Explosive devices present a significant threat to civilian populations and are a severe counter-mobility obstacle for ground forces. With the proliferation of improvised explosive devices into potential U.S. military operating areas, a safer and more efficient method for eliminating the threat is required. U.S. Army forces operating at the brigade and above echelons are generally supported with a variety of unmanned aerial vehicle (UAV) airframes that are capable of conducting reconnaissance and surveillance. These UAVs are faster and more responsive to reports of ground-based explosive devices than explosive ordnance disposal (EOD) teams or route clearance patrols. If UAVs were equipped with a system capable of disarming or destroying explosive devices, the stress on EOD assets would be mitigated and the delaying effect of said explosives on ground forces would be reduced. This research explores the feasibility and utility of using a high-energy laser mounted onboard a UAV platform to defeat ground-based explosive devices. Specifically, this research defines an array of potential targets, characterizes the atmospheric effects in varied weather conditions and climates on such a laser system, and contrasts the size, weight, and power requirements of such a system with the operating capabilities of existing UAV platforms.

ABSTRACT

Explosive devices present a significant threat to civilian populations and are a severe counter-mobility obstacle for ground forces. With the proliferation of improvised explosive devices into potential U.S. military operating areas, a safer and more efficient method for eliminating the threat is required. U.S. Army forces operating at the brigade and above echelons are generally supported with a variety of unmanned aerial vehicle (UAV) airframes that are capable of conducting reconnaissance and surveillance. These UAVs are faster and more responsive to reports of ground-based explosive devices than explosive ordnance disposal (EOD) teams or route clearance patrols. If UAVs were equipped with a system capable of disarming or destroying explosive devices, the stress on EOD assets would be mitigated and the delaying effect of said explosives on ground forces would be reduced. This research explores the feasibility and utility of using a high-energy laser mounted onboard a UAV platform to defeat ground-based explosive devices. Specifically, this research defines an array of potential targets, characterizes the atmospheric effects in varied weather conditions and climates on such a laser system, and contrasts the size, weight, and power requirements of such a system with the operating capabilities of existing UAV platforms.

ACKNOWLEDGMENTS

I'd like to thank my advisors, Professors Keith Cohn and Joseph Blau, for their vast knowledge, assistance, advice, and patience throughout this research. There wasn't a problem that they couldn't help with, and they were always a step ahead of me on this project.

To my wife, Erin, who is my greatest friend, supporter, and editor. I couldn't imagine a better partner in life. Thank you for always helping me to keep it in perspective and not sweat the little things.

Lastly, to my two beautiful daughters, Ava and Louise. You both remind me every day how blessed I am to be a father. Each day is filled with wonderment as your mother and I watch you grow up (but not too fast)!

I. INTRODUCTION

Explosive devices are among the most effective obstacles to ground maneuver in combat. Properly placed, these devices can inflict casualties, deny terrain, steal operational tempo, and threaten civilian populations. According to figures in 2008, approximately 70% of the then 4,163 U.S. combat deaths in Iraq since the start of the war in 2003 were due to roadside bombs [1]. Their proliferation and successes over the past decade ensure that improvised explosive devices (IEDs), land mines, and unexploded ordnance (UXO) remain a threat in future U.S. Army operating environments.

A. GROUND ORDNANCE THREATS

Relative to the weapons used in modern armed forces, IEDs are cheaply produced and readily available to insurgent or terrorist organizations. A bomb maker might expend less than $100 for an IED capable of destroying a light vehicle as compared to more than $100,000 for a conventional U.S. precision munition [2]. Simply put, organizations that employ IEDs are obtaining a comparable tactical effect for a fraction of what the U.S. government pays per application, and they are doing so without the billions of dollars poured into the acquisition and production of new weapon systems.

Land mines and UXO have a detrimental effect on both combat operations and civilian populations. Like IEDs, these munitions excel in the counter-mobility role against ground forces. However, once they have been bypassed, land mines and UXO still present a significant threat to civilian populations in the vicinity. As of 2003, Soviet land mines from the war in Afghanistan that ended in 1989 still inflicted approximately 300 civilian casualties per month [3]. Unfortunately, even modern armed forces continue to leave behind these dangerous explosives due to limited disposal assets and competing priorities. Apart from the broader humanitarian argument, this threat presents a more immediate challenge to the U.S. Army if the mission specifically entails protection of the civilian population.

B. CURRENT REMOVAL METHODS

Ground-based explosive devices are undoubtedly a problem that the U.S. Army needs to solve safely, effectively, and cheaply in order to be successful on future battlefields. Current removal methods rely on the use of highly specialized units and equipment that may not always be available and are expensive to field. Directed energy is a potential solution to the threat posed by these devices. The Department of Defense recognized the utility of lasers on the battlefield as far back as the 1960s [2] and has since committed funding to multiple projects as a means of combatting a variety of threats to friendly forces.

C. POTENTIAL ADVANTAGES OF DIRECTED ENERGY EMPLOYMENT

In 2004 the U.S. Army demonstrated that in-flight mortar rounds can be destroyed using a ground-based high energy laser. The Mobile Tactical High Energy Laser (MTHEL) destroyed seven medium in-flight mortars during testing, which included a three-round salvo [4]. In 2008 the U.S. Special Operations Command mounted a 100 kW laser on an AC-130 gunship and dubbed it the Advanced Tactical Laser (ATL). The ATL was intended to function as a direct fire weapon against ground targets, which included a remotely controlled vehicle in one particularly successful test [5]. Finally, in 2010 the U.S. Air Force succeeded in destroying an in-flight ballistic missile using the Airborne Laser (ABL), a megawatt-class laser mounted inside a Boeing 747 [5] (Figure 1).

1106 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 1. YAL-1A Airborne Laser. Source: [6].

Although the MTHEL, ATL, and ABL were successful during testing in ideal conditions, all three projects were cancelled for the same general reasons. Each system utilized a large chemical laser that, aside from the massive size (the MTHEL required several oversized trailers to move across the battlefield [5]), required the transportation, storage, and handling of dangerous and expensive chemicals. Additionally, each project was built on the assumption that the laser would be in the right location at the right time to strike a fast moving target. In the case of the ABL, five to seven Boeing 747s would have to maintain a presence near a missile launch site for a successful interdiction [5]. Such a quantity of large, slow aircraft loitering over enemy controlled territory would be an irresistibly attractive target. In order for directed energy to be successful in tactical engagements, lasers must be smaller, logistically simple, and mobile.

This study models the use of solid-state lasers mounted on unmanned aerial vehicles (UAVs) against surface-laid ground ordnance. Solid-state lasers operate by electricity instead of chemical reactions and are generally much smaller than chemical lasers. Current solid-state lasers also produce much less optical output power than their chemical relatives, but this may be offset by the intended application. While the MTHEL, ATL, and ABL required high irradiance over a short dwell time to be successful, a solid-state laser that targets ground ordnance has the luxury of an extended engagement period

1107 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

since IEDs, land mines, and UXO don't move. Additionally, the explosives used in these potential targets self-ignite at temperatures of a few hundred kelvins; this is considerably lower than the temperatures needed for other target types (e.g., to melt through missile casings). Thus, the irradiance, and consequentially the output power, of the laser can be reduced while still achieving the desired effect.

UAVs are ideal platforms for destroying ground ordnance with solid-state lasers. Currently, a brigade combat team (BCT) in the U.S. Army fields four RQ-7B Shadow UAVs that are intended to provide 24-hour geographic coverage for that BCT's area of operations. The availability of UAVs only increases at each higher echelon, with the MQ-1C Gray Eagle (Figure 2) fielded at the division-level. This means that there is a persistent and flexible UAV presence within every area of operations that could potentially put a laser at the right location and time to be effective against the ground ordnance threat. Additionally, UAVs have a large stand-off distance from ground targets that eliminates the need to put soldiers or expensive equipment within the blast radius of said ground ordnance. The challenge for using UAVs in this intended application lies in the fact that all of these platforms have limited capacity for the size, weight, and power (SWaP) requirements inherent to solid-state lasers.

Figure 2. MQ-1C Gray Eagle. Source: [7].

1108 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Aside from the engineering challenges associated with mounting lasers on UAVs, an air-to-ground directed energy system must consider atmospheric propagation effects such as diffraction, scattering, absorption, and turbulence [2]. Consequentially, the required beam output power must be designed to overcome these effects and cross the lethal fluence threshold at the target.

D. OVERVIEW OF STUDY

This study identifies the energetic compounds used in common IEDs, surface-laid land mines, and pieces of UXO in order to estimate the lethal fluence needed for these compounds. Based on this information, the study then estimates the laser power needed to achieve the lethal fluences over acceptable dwell times for various atmospheric conditions. Finally, the study discusses the feasibility of using solid-state lasers against ground ordnance based upon SWaP considerations and UAV platform availability.

II. OVERVIEW OF DIRECTED ENERGY WEAPONS

As it is applied to weaponry, the term “directed energy” can have a multitude of meanings. For example, the deposition of energy on a target can be accomplished through the use of microwaves, particle beams, or high energy lasers (HELs). However, for directed energy weapons to be effective, the delivery method, target parameters, platform allowances, and propagation medium must be such that the desired result on the target is achieved. HELs are currently a highly active subject of study for defense applications and will be the focus for this research due to their relative advantages over other types of directed energy weapons.

A. HISTORY

The development of HELs as weapons began almost immediately following the invention of the first laser in 1960. The Soviet Union started researching the feasibility of HELs defeating intercontinental ballistic missiles during their reentry phase in 1965, going so far as establishing a town of 20,000 people at Raduga to conduct research and testing [8]. The United States followed when Ed Gerry created a gas dynamic CO2 laser with an output power of 100 kW in 1968 [8]. Each branch of the armed forces began funding their own projects tailored for their specific requirements.

The next major advancement came from the U.S. Navy with the creation of the Navy ARPA Chemical Laser (NACL), which was a multi-hundred kilowatt-class chemical laser. The NACL successfully destroyed tube-launched optically-tracked wire-guided (TOW) missiles in-flight in 1978 and led to the development of the Mid-IR Advanced Chemical Laser (MIRACL) in 1980, which was the world’s first megawatt-class laser [9]. However, chemical lasers are not ideal for ship-based applications due to the fuels required and exhaust they create. Additionally, the less-than-ideal output wavelength produced by these lasers were prone to atmospheric absorption, which resulted in decreased irradiance at the target and thermal blooming. These factors contributed to a hiatus in Navy HEL design until a suitable alternative with comparable power outputs could be developed. In 2014, the 30 kW AN/SEQ-3 Laser Weapon System (LaWS) (Figure 3) was installed on

1111 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the USS *Ponce* and successfully demonstrated the ability to destroy small boats and UAVs [10]. The LaWS is a solid-state system that circumvents the challenges of chemical lasers at the expense of an output that is lower by at least an order of magnitude.

Figure 3. LaWS Onboard the USS *Ponce*. Source: [11].

The U.S. Air Force created the Airborne Laser Lab (ALL) with a 100 kW class gas dynamic laser mounted in a KC-135 aircraft, which succeeded in destroying AIM-9 missiles and BQM-34 drones during testing in 1983 [8]. Due to the relatively low electrical power requirements of chemical lasers, this type of system was the basis of the Space Based Laser (SBL) program that began in 1989 with the purpose of defeating ICBMs in their boost phase. The program intended to conduct a successful demonstration by 2012 [9], but was cancelled in 1991 [8]. Building on the successes of the ALL and prompted by the cancellation of the SBL, the Air Force began work on the ABL program in 1994, which incorporated a megawatt class laser in a Boeing 747 [8]. As mentioned in the previous chapter, the ABL was successful during testing in its intended purpose of destroying ballistic missiles in the boost phase, but the requirement of putting the laser within range of a target and program costs led to its cancellation.

1112 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Meanwhile, the U.S. Army took an interest in using ground-based HELs to counter indirect fire. Research for the Tactical High Energy Laser (THEL) began in 1996 as a joint venture between the United States and Israel as a means to interdict Katyusha rockets [9]. The THEL achieved successes in testing against rockets in 2000 and against mortar rounds in 2004, but proved too expensive and unwieldy on the battlefield. The THEL and its offshoot, the MTHEL, were cancelled due to a lack of available funding. Although the Army lost interest in the THEL and MTHEL, it did not lose interest in ground-based HEL applications and by March 2003 deployed the Zeus HMMWV Laser Ordnance Neutralization System (Figure 4) to Afghanistan to assist with UXO removal [12]. That version of the Zeus incorporated a 500 W neodymium yttrium aluminum garnet (Nd:YAG) solid-state laser [9] with an effective range of 300 meters [12]. During its six-month deployment to Bagram Air Field, the Zeus negated over 200 pieces UXO, including a record-breaking 51 pieces of UXO in less than 100 minutes [12]. The performance of the Zeus demonstrated the feasibility of using a HEL to destroy ground ordnance.

Figure 4. Zeus HMMWV Laser Ordnance Neutralization System. Source: [13].

1113 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Nearly 60 years of HEL design and testing revealed several lessons regarding their use as weapons. Although chemical and gas lasers are capable of achieving higher output powers at relatively better efficiencies, they are also unwieldy, if not downright dangerous to the user in battlefield applications. Solid-state lasers are currently receiving the most attention due to innovations that have increased their power output, their safer electrical "fuel," and their ideal wavelength for atmospheric propagation. This research will focus primarily on solid-state systems due to these reasons, especially considering the projected application of using them onboard UAVs. As the Zeus device demonstrated, only modest output power is needed to affect the desired result against ground ordnance.

B. ADVANTAGES AND DISADVANTAGES

Solid-state HELs have numerous advantages when compared to conventional ballistic weapons. Perhaps the most significant is that the beam propagates at the speed of light. The next major advantage of HELs is the cost per engagement associated with using the weapon. Ballistic munitions are expensive and only available in limited quantities; armored vehicles, aircraft, and ships can only carry a finite number of rounds, bombs, or missiles. On the other hand, lasers only cost the fuel required to generate electricity for each engagement; a typical cost of less than a dollar compared to thousands of dollars for conventional munitions. Finally, HELs can generally outrange conventional line-of-sight munitions if the laser is designed to overcome the effects of scattering and absorption that lead to beam extinction.

Solid-state HELs do come with some inherent disadvantages that have so far prevented their widespread deployment. Compared to ballistic munitions and chemical or gas lasers, solid-state HELs are inefficient. The typical "wall-plug" efficiency for solid-state systems is on the order of 20% to 30%, which necessitates an electrical power source capable of providing hundreds of kilowatts for each engagement. This inefficiency leads to heat generation in the lasing medium that must be actively removed. Cooling systems that can effectively dissipate the heat add additional power and weight requirements. Additionally, any HEL system is more susceptible to atmospheric effects, such as precipitation and haze, than conventional ballistic munitions. Since the defeat mechanism

1114 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

employed by HELs typically involves heating of the target, a laser must also overcome the energy loss resulting from light reflected by the target's surface.

Considering the objective of this research, airborne HELs are an attractive option for defeating explosive devices. If explosive ordnance disposal (EOD) personnel decide that a device can be rendered ineffective in-situ, there are a variety of methods available that include disruptors, anti-munition rifles, de-armers, explosives, fuze removal, or fuze immunization [14]. All of these options require deployment of EOD teams and potentially place these specially trained personnel at risk (Figure 5). Simply the loss of time incurred by friendly forces is often enough to justify the emplacement of explosive devices by the enemy. By requiring friendly forces to adjust from a proactive posture to a reactive one, an enemy that employs these devices steals the tactical initiative. Conversely, HELs (particularly airborne systems) enable the discoverer of an explosive device to act expeditiously and with pinpoint precision. Barring prohibitive weather conditions, UAVs continuously occupy the airspace of a U.S. Army unit's area of operations. The operational cost in time incurred by a friendly unit that encounters an explosive device could potentially be cut from hours (waiting on an EOD team or combat engineers to arrive) to minutes (the time it takes to direct an already airborne clearance asset to the location). This is not to say that using airborne HELs to dispose of explosive devices completely negates the need to have EOD assets available; weather occasionally grounds UAVs, disposing of a device in-situ is not always a possibility, and it is likely infeasible to use a HEL to defeat buried devices. However, it does provide another option for ground commanders to leverage based on the merits of the tactical situation.

1115 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 5. EOD Personnel Train to Dispose of an IED. Source: [15].

C. PROJECTED APPLICATIONS

HEL systems have demonstrated success in testing and limited field deployments, and the next generation of these weapons are currently in the design phase. The Navy established their Directed Energy Program Office within the Program Executive Office for Integrated Warfare Systems in August 2016 [16]. In a February 2017 Federal Business Opportunities posting, this office requested industry capabilities for a new program that consists of a 60 kW HEL with counter-ISR dazzling capability and is capable of operating on an Arleigh Burke-class guided missile destroyer [16]. The Air Force is currently funding a demonstration called SHIELD, which intends to integrate a solid-state HEL with an output power in the tens of kilowatts range on a fighter-size aircraft by 2020 [17]. The Army is investing in its High Energy Laser Mobile Demonstrator, a ground-based system primarily intended to counter indirect fire and UAVs and is capable of being transported by a relatively small armored vehicle such as a Stryker personnel carrier [18]. All of these projects underline the increased interest in HEL weapons, particularly solid-state systems, and the great advances that have been made in HELs since the first laser was invented in 1960.

1116 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

III. CHARACTERIZATION OF HIGH EXPLOSIVE TARGETS

Land mines, UXO, IEDs, and most other high explosive devices share the same basic components and principles of operation. It is this similarity that enables a single clearing system, such as a HEL, to be effective against a wide range of potential threats. Accordingly, three different explosive devices serve as target profiles for this research: the TM-83 anti-vehicle (AV) land mine, the PTAB-2.5M high explosive anti-tank (HEAT) sub-munition, and a Composition C-4 based IED. These devices were selected due to how well they characterize each category of munition (surface-laid land mine, UXO, and IED, respectively), current usage, and variety in construction and materials. This chapter will describe the fundamental components of high explosive devices and will detail the defeat mechanism selected for their removal using a HEL.

A. COMPOSITION

Explosive devices generally consist of four basic components; the detonator, the booster charge, the main charge, and the casing. The detonator is the component that triggers a detonation and can come in many forms. Conventional munitions such as bombs and artillery shells that are commonly found as UXO contain a fuze or a timer for this purpose. Land mines and IEDs make use of switches, sensors, wired detonators, or wireless receivers (Figure 6). Regardless of the form, the detonator is ultimately what initiates an explosive reaction in the booster charge.

1117 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 6. IEDs Captured in Afghanistan with Detonators Mounted on Top. Source: [19].

Booster charges are an intermediary material between the detonator and the main charge. Detonators usually do not provide enough energy to trigger an explosive reaction in the most common types of high explosives, so a less stable explosive is used to create a shock wave that will detonate the main charge. The main charge is what gives a device its explosive power and is usually the largest internal component (Figure 7). Common military-grade explosives used for main charges include trinitrotoluene (TNT), research department explosive (RDX), and high melting explosive (HMX). Perhaps the most commonly used combination of these explosives is Composition B-3, which is a 60% RDX and 40% TNT mixture [20].

1118 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

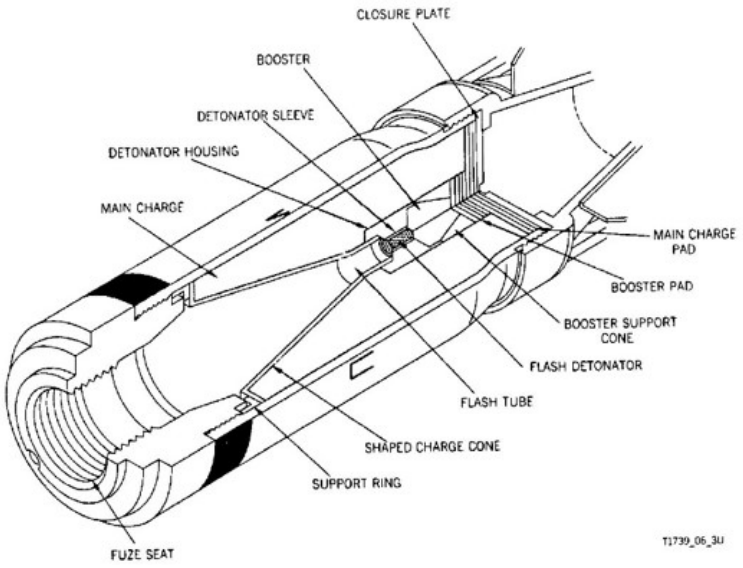

Figure 7. Cross-sectional Diagram of a PTAB-2.5M HEAT Sub-munition Depicting Booster and Main Charges. Source: [21].

The final basic component found in most explosive devices is the casing. The number of combinations of materials, shapes, and fragmentation patterns found in casings is effectively limitless. Metal casings provide durability and double as shrapnel when the device detonates, but are easier to detect with the magnetic scanners commonly employed by clearing assets. Conversely, plastic casings are difficult to detect, but require more care during handling and must be filled with some form of shrapnel to maximize effectiveness. Of particular note is the modern use of the explosively formed penetrator (EFP), which is a circular concave piece of malleable metal (usually copper) that is mounted over the main charge. Upon detonation, the explosive forces reshape the metal into a molten dart-like projectile capable of penetrating most types of armor. The TM-83 AV land mine is an example of a device that produces an EFP (Figure 8).

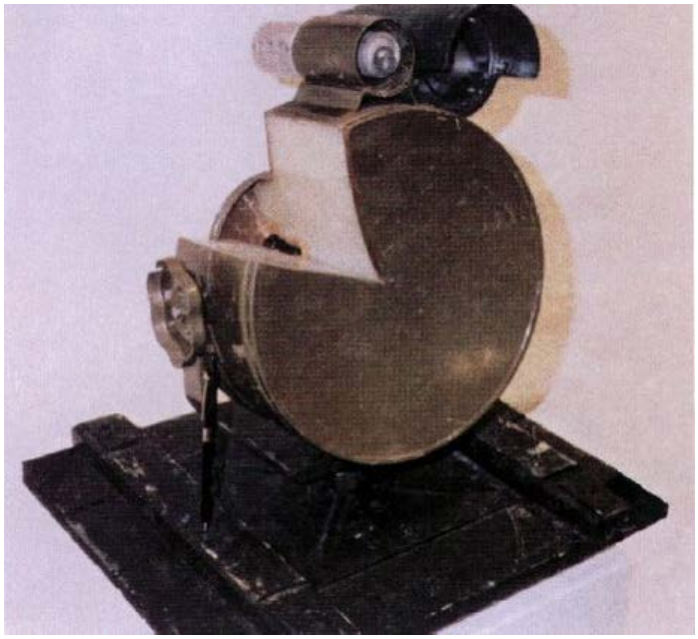

Figure 8. TM-83 AV Land Mine with Triangular Cutout Exposing Main Charge. Source: [22].

B. HIGH EXPLOSIVE PROPERTIES

The potential energy of an explosive material is analogous to a boulder resting on the edge of a cliff [23]. Initially, a great deal of energy is expended to move the boulder to this position. For explosives, this is referred to as the heat of formation. Once the boulder is at the edge, only a slight nudge is required to push it over and expend the high potential energy stored within. Accordingly, this nudge is known as the activation energy. The relatively rapid expenditure of energy during this detonation is what differentiates explosives from other high-energy materials such as wood, coal, or oil. In the case of coal versus HMX, the power output is a difference of nine orders of magnitude [23].

In this research, the "nudge" is the defeat mechanism used to destroy the designated targets. The HEL acts as an energy pump by depositing a portion of its energy in the form of heat on the surface of the target (the rest of its energy is reflected depending on the surface material). As the HEL deposits more energy over time, the temperature of the casing rises as heat diffuses through it and ultimately reaches the main charge contained

1120 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

within. The heat transfer in both the casing and main charge is easily modeled with the well-known heat diffusion equation:

$$\rho c_p \frac{\partial T}{\partial t} = \nabla \cdot (\kappa \nabla T) \tag{1}$$

where ρ is the density of the casing or main charge, c_p is the specific heat capacity, T is the temperature, and κ is the thermal conductivity. Once the interface between the casing and main charge reaches an explosive property known as the autoignition temperature, the main charge will begin expending its potential energy in a manner similar to the falling boulder. While this mechanism will not produce a full detonation, it will render the explosive device ineffective by forcing the main charge to deflagrate [24]. This removal method can actually be more favorable than full detonation if the explosive device is located in close proximity to valuable infrastructure or populated areas.

C. EFFECT OF HEATING

As heat deposited by the laser beam accumulates at the interface between the casing and the main charge, the explosive material will undergo a chemical reaction and release its stored potential energy in the form of additional heat. The rate at which the explosive releases heat as it undergoes the chemical reaction is known as the thermal rate constant. While the constant is initially a relatively small value, it will grow exponentially as the heat deposited by the HEL combines with the accumulating heat emitted by the explosive. The empirical Arrhenius Law is probably the oldest yet best-known model for expressing this thermal rate constant *k(T)* [25]:

$$k(T) = Ae^{-\frac{E}{k_B T}} \tag{2}$$

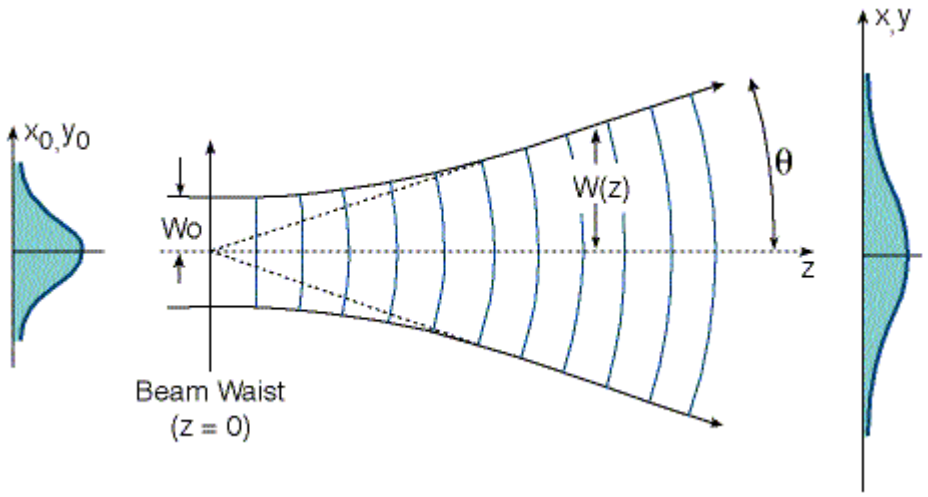
where A is a pre-exponential constant, E is the activation energy, k_B is the Boltzmann constant, and T is the temperature of the explosive material. The pre-exponential constant is unique to a given chemical reaction and is often determined experimentally with units similar to the thermal rate constant (with magnitude typically on the order of 10^{10}) [26]. When the temperature is low, this pre-exponential factor is suppressed. However, as the temperature of the explosive rises relative to its activation energy, the extremely large pre-exponential factor causes the thermal rate constant to increase dramatically. The complete

1121 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

model for predicting heat transfer in an explosive material is a combination of both the heat diffusion equation (Equation 1) and the Arrhenius Law (Equation 2) and appears as:

$$\rho c_p \frac{\partial T}{\partial t} = \nabla \cdot (\kappa \nabla T) + \rho Q Z e^{-\frac{E}{k_B T}} \tag{3}$$

where Q is the heat of decomposition and Z is the characteristic reaction rate of the explosive [27]. The product of the explosive's density, heat of decomposition, and characteristic reaction rate is the pre-exponential constant A annotated in Equation 2. The Arrhenius term acts as a heat source in the heat diffusion equation. Once the temperature T reaches the autoignition temperature, the Arrhenius term dominates and acts as a "positive feedback loop," producing a "run-away" reaction. The predicted autoignition temperature for Composition B-3 is approximately 800-K [20], while the predicted value for Composition C-4 is approximately 650-K [20].



1122 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

IV. LASER BEAM PROPAGATION THROUGH THE ATMOSPHERE

The environment through which a laser beam propagates can dramatically affect the beam's properties from origin to termination. The Earth's atmosphere is full of molecules and particles that can influence a laser beam, and this fact must be accounted for in any system that intends to propagate over a meaningful distance. This chapter will describe those effects as well as their impact on an airborne laser system engaging ground-based targets.

A. VACUUM PROPAGATION

Before considering the effects of atmosphere on beam propagation, it is first necessary to understand how a beam propagates under ideal conditions. Due to the wave nature of light, any light source directed through an aperture will experience divergence. This will cause the radius of the beam, known as the beam waist, to increase in accordance with the divergence angle (Figure 9).

The divergence angle is represented by θ. Note the Gaussian profiles in the margins depicting the decrease in beam irradiance as propagation distance increases.

Figure 9. Beam Waist *w* as a Function of Propagation Distance *z*. Source: [28].

1123 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The beam waist size, divergence angle, and beam wavelength determine the quality of the laser beam. This parameter is known as the beam quality factor and is calculated with the equation:

$$M^2 = \frac{w_0 \pi \theta}{4\lambda} \tag{4}$$

where M^2 is the beam quality factor, w_0 is the beam waist size, θ is the divergence angle, and λ is the beam wavelength [29]. A beam quality factor of 1 indicates an ideal Gaussian irradiance profile. However, current lasers are not perfect and will produce beams with a factor greater than 1. The greater the value of the beam quality factor, the less irradiant the laser beam will be at the target. For this research, a beam quality factor of 3 is used for simulations in order to produce more realistic results.

The size of the laser beam director itself can also significantly impact the qualities of the beam. The effect of beam director diameter on beam waist can be approximated with the equation:

$$w_0 \approx M^2 \left(\frac{2\lambda z}{\pi D} \right) \tag{5}$$

where w_0 is the beam waist size, M^2 is the beam quality factor, λ is the beam wavelength, z is the propagation distance, and D is the beam director diameter [30]. As the beam director diameter increases, the beam waist will decrease and produce a more irradiant beam profile at the target. However, regarding the use of lasers on airborne platforms, it is necessary to keep the beam director as small as possible due to limited space availability and payload capacity. In these simulations, the beam director diameter is set at 25 cm in order to accurately represent a system capable of being mounted to a UAV.

B. EXTINCTION

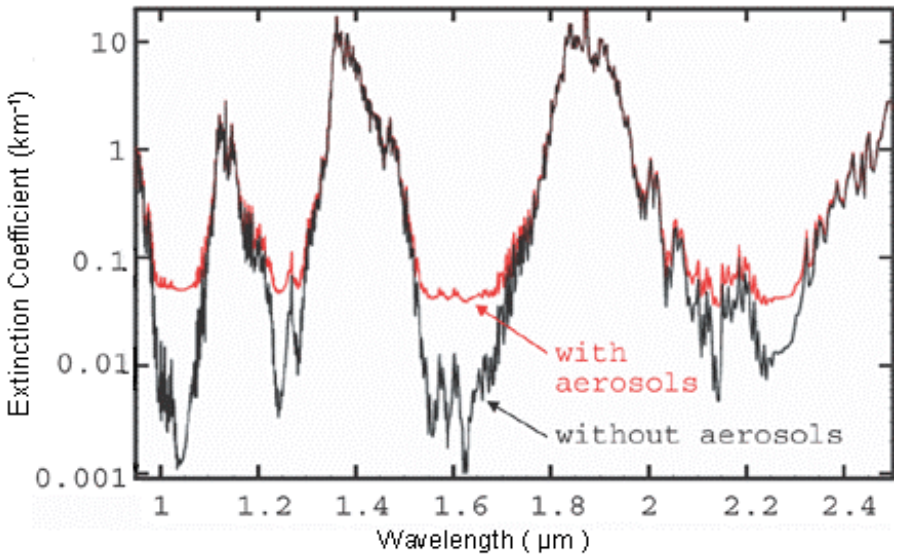
Atmospheric extinction of a laser beam is the result of two separate phenomena. The first of these is absorption, in which atmospheric molecules and aerosol particles absorb incoming photons and thereby decrease the irradiance of the laser beam. Absorption is dependent on the wavelength of the photons and the types of particles present. Since Earth's atmosphere is composed of numerous varieties of molecules and particles, there are only a few narrow wavelength bands that are favorable for beam propagation. Many

1124 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

solid-state lasers currently designed for directed energy applications have wavelengths near 1 μm, which is within a "window" in which light propagates with minimal absorption.

The second effect that causes beam extinction is scattering. Particles in the atmosphere with sizes comparable to the wavelength of light will deflect light rays in random directions. This effect is evident in white clouds, in which water vapor scatters incident light with wavelengths across the visible spectrum. Particles generated as dust or by pollution also scatter light, resulting in a hazy atmosphere (Figure 10).

Figure 10. Haze Created by Atmospheric Scattering of Light by Aerosol Particles. Source: [31].



Laser beam extinction is modeled as an exponential decay. The Beer-Lambert Law provides the mathematical foundation with the function:

$$P(z) = P_0 e^{-\varepsilon z} \tag{6}$$

where *P(z)* is the beam's power as a function of propagation distance, *z* is the propagation distance, P_0 is the initial power, and ε is an extinction coefficient that accounts for wavelength-specific scattering and absorption information and also depends on location, time of day, aerosol concentration, etc. [32]. For the intended application of defeating explosive devices, the extinction coefficient must be as small as feasible, which is largely

1125 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

accomplished by selecting a beam wavelength of approximately 1 μm that tends to minimize extinction (Figure 11).

The red plot includes the presence of aerosols. Note the relatively low extinction coefficient values at approximately 1 μm and 1.6 μm.

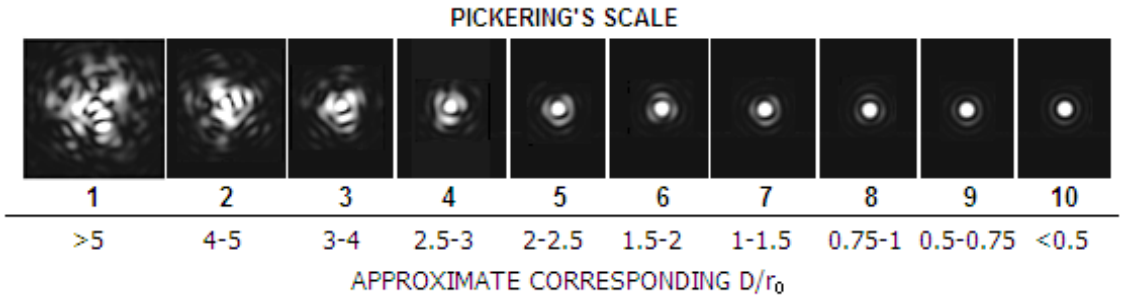
Figure 11. Effect of Wavelength on Beam Extinction. Source: [33].

C. TURBULENCE

As the sun's radiation heats the atmosphere and Earth's surface, it creates differences in air temperature. Accordingly, these cells of air have different densities and pressure that alter their optical indices of refraction. When a light ray transmits between different cells, variations in the indices of refraction cause the light ray to deflect. In addition to this deflection, turbulent cells that are smaller than the laser beam's cross-sectional area will cause portions of the beam to diverge. This divergence results in a loss of coherence, as portions of the beam become out of phase and destructively interfere with each other. The ultimate consequence of turbulence is a distorted, larger, and less intense time-averaged beam spot on the target.

Turbulence is quantified by the refraction structure parameter C_n^2, which is a measure of the change in the air's index of refraction over distance:

1126 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING



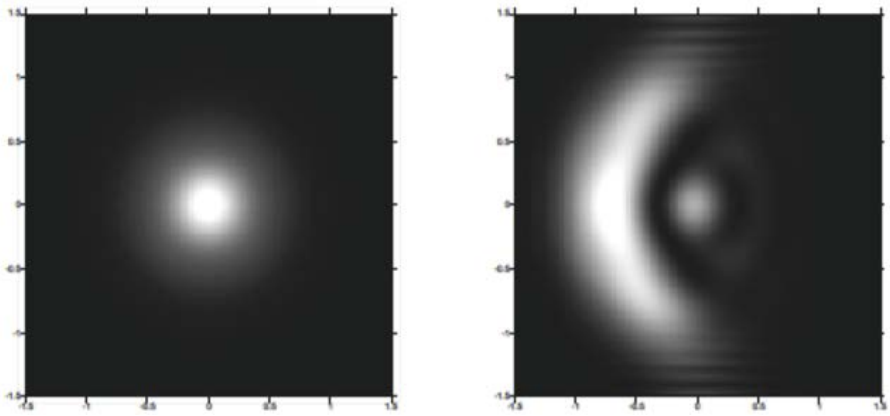
$$C_n^2 = \frac{\overline{[n(x) - n(x+r)]^2}}{r^{2/3}} \quad (7)$$

where *n(x)* is the index of refraction and *n(x+r)* is the index of refraction at range *r* [34]. A value of 10^{-14} $m^{-2/3}$ indicates stronger turbulence, while a value of 10^{-17} $m^{-2/3}$ indicates weaker turbulence.

The refraction structure parameter is of little analytical value by itself, but can be used to estimate the effect of turbulence on beam coherence at the target. The Fried parameter is an estimation of the diameter over which a laser beam maintains transverse coherence throughout a desired propagation distance:

$$r_0 = [0.423(2\pi / \lambda)^2 \int_0^z C_n^2(z)dz]^{-3/5} \quad (8)$$

where r_0 is the Fried parameter, λ is the wavelength, and z is the propagation distance [32]. This formula incorporates C_n^2 along the beam path. As the value of C_n^2 increases, the value of the Fried parameter decreases. For example, given a beam wavelength of 1 μm, a constant C_n^2 value of 10^{-14} $m^{-2/3}$, and a propagation distance of 3 km, the Fried parameter would be approximately 2.4 cm. Under these conditions, any laser beam that is greater than 2.4 cm at its source (established by the beam director diameter) will be significantly affected by turbulence (Figure 12).



Pickering's scale provides a visual approximation of the relationship between the Fried parameter and beam director diameter (denoted as *D*). Each scale number corresponds to a representation of a beam cross-sectional area. As D/r_0 becomes greater than 1, the beam's area will increase and break apart.

Figure 12. Pickering's Scale. Source: [35].

1127 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

D. THERMAL BLOOMING

A laser beam itself can modify the properties of the air it is propagating through. As photons are absorbed by aerosols and molecules along the beam path, energy is released in the form of heat. This heat in turn alters the air's index of refraction by causing the air to expand and become less dense. As the beam continues to propagate through this modified air, it will begin to diverge more quickly than would otherwise be expected via this thermal blooming process [32]. This phenomenon is highly susceptible to temperature-altering effects such as wind. If wind blows across a beam path that is experiencing thermal blooming, it will cool the incident side of the beam and push heated air to the opposite side. The beam will then "bend" into the cooler, and therefore denser, side of the "lens" (Figure 13).

The image on the left depicts a beam profile without wind, while the image on the right depicts beam "bending" caused by a wind blowing from left to right.

Figure 13. Effect of Wind on Thermal Blooming. Source: [36].

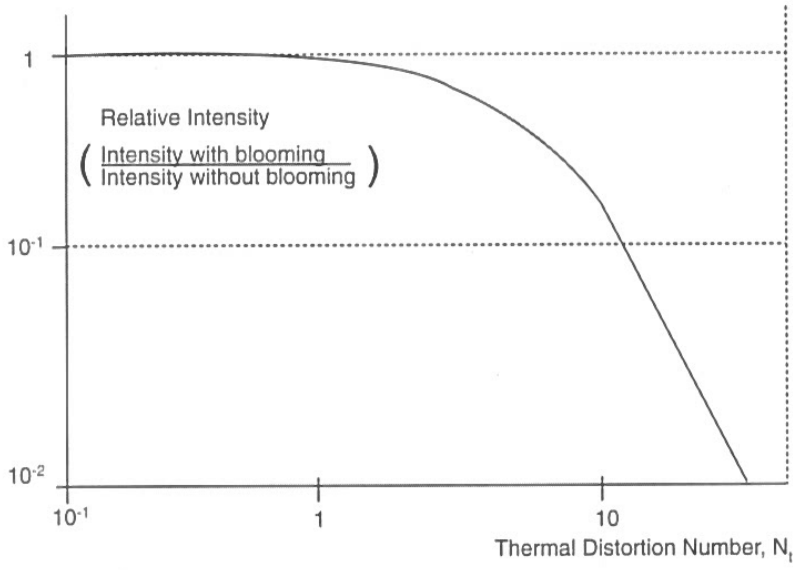
Thermal blooming is roughly characterized through a dimensionless thermal distortion factor, N_t:

$$N_t = \frac{-(dn/dT)}{n\rho c_p} \times \frac{KIz^2}{vr} \tag{9}$$

where n is the air's index of refraction, (dn/dT) is the rate of change in the index of refraction as a result of temperature change, ρ is the air's density, c_p is the heat capacity of

1128 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the air, *K* is the absorption coefficient of the air, *I* is the laser beam's irradiance without thermal blooming, *z* is the distance of propagation, *r* is the beam's radius, and *v* is the crosswind's speed [32]. A larger thermal distortion factor indicates greater beam distortion and decreased intensity at the target. If the crosswind speed or beam radius increase, the thermal distortion number will decrease. However, increasing beam irradiance or propagation distance has the unwanted effect of increasing the thermal distortion number. Figure 14 depicts the effect that the thermal distortion number has on the relative intensity of the laser beam.



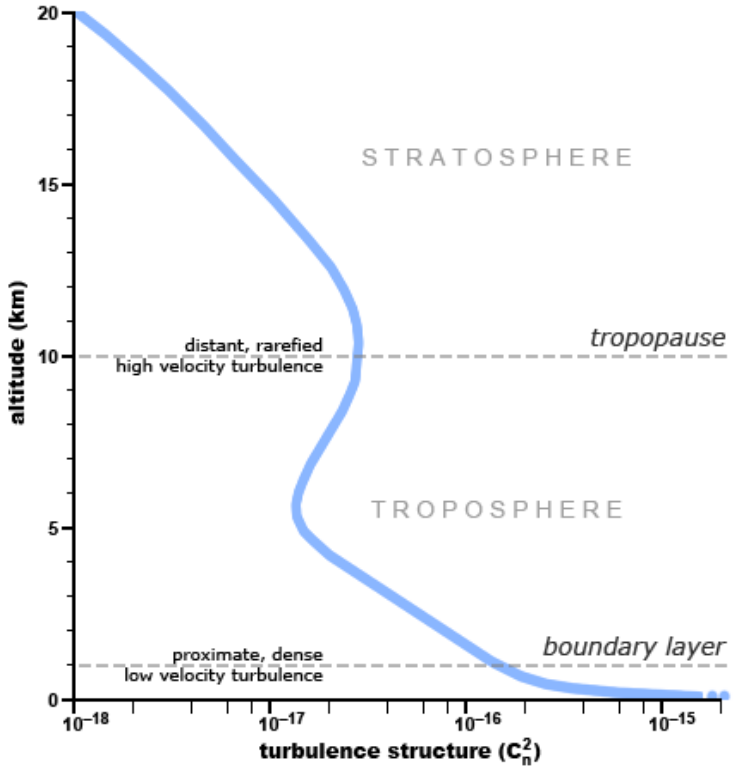


Figure 14. Relationship between Thermal Distortion Number and Relative Intensity. Source: [32].

E. ELEVATION EFFECTS

Using a HEL on an airborne platform to engage ground-based targets has several advantages relative to ground-based lasers. Turbulence is often dramatically reduced at elevation since the platform is further from the ground, and consequently, further from heat sources and surface effects (Figure 15). Although the laser beam is still required to propagate through low-altitude atmosphere as it nears the target, the path over which turbulence is a factor is greatly diminished and restricted to the terminal portion. A ground-

1129 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

based laser beam must suffer the effect over its entire path, including at the beam's origin where it has the greatest effect on the rest of propagation.

Smaller UAVs operate at lower altitude (approximately 2 km) while larger UAVs operate at higher altitude (between 15 km and 18 km).

Figure 15. Effect of Altitude on Atmospheric Turbulence. Source: [37].

Additionally, air density decreases with altitude, which exponentially decreases absorption and increases beam irradiance at the target. The desire to use UAVs as the airborne platform of choice in this research also introduces an advantage regarding thermal blooming. All UAVs currently employed by the U.S. Army are fixed wing aircraft that cannot remain stationary in flight. This means that any laser beam originating from a UAV platform will constantly be moving through unheated air and experience a relative wind proportional to the velocity of the UAV itself. These two factors effectively eliminate thermal blooming as a consideration for the intended application of this research.

1130 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

V. METHODOLOGY

This research simulates air-to-ground laser engagements of ground ordnance using computer-based MATLAB code with user-defined parameters. This chapter will address the variety of parameters used and the reasons for their selection. It will also identify existing simulations used, upon which this research is partially based.

A. TARGET PARAMETERS

Three different types of ground ordnance are modeled in this research: a land mine, IED, and piece of UXO. While it would be impossible to model every explosive device currently in use, the established target profiles emphasize generalized distinctions between the three types. The fundamental differences between these categories are target geometry, outer casing, and explosive material.

1. Geometry

All three types of target have myriad geometries available to choose from. However, the problem can be simplified when approached from the context of this research. Any laser beam intentionally aimed at an object of known range will be deliberately focused in order to reduce its effective area on the target. This focus spot acts as a source term for the heat diffusion equation previously mentioned in Chapter III (Equation 1). The profile of the laser beam is assumed to be a Gaussian distribution modeled by the equation:

$$S = I_{pk}(1-R)e^{-\frac{r^2}{w_{tot}^2}} \tag{10}$$

where S is the source term for the heat diffusion equation, I_{pk} is the peak irradiance of the laser beam, R is the reflectivity coefficient of the target's surface, r is the radial coordinate of the profile, and w_{tot} is the beam waist size. For these simulations, the reflectivity coefficient is assumed to have a value of 0.1, since most explosive devices are intentionally coated in dark non-reflective materials that conceal them within surroundings.

1131 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Ideally, the beam waist is minimized at the target due to focusing (although this can be affected by atmospheric conditions). As a characteristic example, the circular face of the TM-83 AV land mine has a radius of 12.5 cm, with a surface area of approximately 490 cm^2 [22]. Assuming that a typical laser beam has a waist of 3 cm at the target and a cross-sectional area of approximately 28 cm^2, it is reasonable to neglect the effect of geometry on the target's heating since the beam area constitutes less than 6% of the total irradiated surface. Therefore, a standard geometry is used for all three target types during simulations, which consists of a right circular cylinder of 10 cm radius and 10 cm height, with one circular surface being irradiated by the laser beam at its center.

2. Outer Casing

There is a wide variety of casing materials used in explosive devices, which principally reduces to the distinction of plastic versus metal. As previously discussed, metal casings provide for safer handling of the device and have the added effect of increasing shrapnel upon detonation. Steel is a commonly used metal for this purpose and is the material used in many military-grade munitions. Due to this fact, it is appropriate to select steel as the outer casing for the land mine and UXO target profiles, since both are characteristically employed by military forces. Since the thickness of these casings is highly variable between specific devices, a generalized thickness of 5 mm is used for the land mine profile, while a thickness of 2.5 mm is used for the UXO profile. As the casing material is the same in both of these profiles, the simulation results illustrate the effect that casing thickness has on the required dwell times.

Plastic casings are more difficult to detect on the battlefield and are readily available to amateur explosives manufacturers, such as the insurgents and terrorists that employ IEDs. Although IEDs can and have been encased with metal, high density polyethylene is used in this research as the outer casing for the IED profile in order to demonstrate the effect that casing material has on required dwell times. A generalized thickness of 5 mm is used for the IED profile in order to make it comparable to the steel-encased land mine profile, also of 5 mm thickness. Table 1 includes a comprehensive listing of the all outer casing thermal property values used during actual simulations.

1132 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 1. Outer Casing Thermal Properties. Source [38].

Material	Density, ρ [kg/m^3]	Thermal Conductivity, κ [W/(m*K)]	Heat Capacity, c_p [J/(kg*K)]
Steel (Plain)	7854	60.5	434
Polyethylene (High Density)	959	0.43	2000

3. Explosive Material

Since World War II, RDX is one of the most commonly used components in military-grade high explosives. It is a majority ingredient found in several Composition A, B, and C mixtures widely used by U.S. armed forces (up to 98.5% in Composition A-3, 60% in Composition B-3, and 95% in Composition C-3) [20]. Its thermochemical properties are widely studied and publicized, making it a reasonable assumption that most professional and amateur military forces employ it or its derivatives to some extent. This fact makes it an ideal material to include in generalized models of all three target types, and the thermal property values needed to do so are included in Table 2. These parameters are discussed in the context of the heat diffusion equation in Chapter III (Equation 3).

Table 2. RDX Thermochemical Properties. Source [39].

1800	0.29	2093	2.09	199	$10^{18.5}$

B. ATMOSPHERIC PARAMETERS

In order to establish the atmospheric conditions under which to conduct simulations, it is necessary to consider climate type and weather. Since the combination of these two factors result in a countless number of geographic locations to model, it is necessary to also consider the likelihood that a particular region could become the home of

1133 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

an armed conflict within the near future. Seoul, South Korea and Kandahar, Afghanistan provide highly contrasting climatic conditions with potential for continuing and future military operations. Seoul possesses a temperate climate [40], which is well distinguished from the arid desert climate of Kandahar [41]. The contrast provided by these locations demonstrates the effect that climate has on the required target dwell times.

With climates established, it is also necessary to specify the exact weather conditions under which the simulations will be performed. In order to exemplify the extremes under which engagements could occur, clear and precipitous weather conditions are modeled. Clear weather enables ideal laser beam propagation, while the presence of large water droplets models the most non-ideal condition under which to engage ground ordnance with a laser. As an intermediary, hazy weather conditions are modeled in order to demonstrate the effect of aerosols on the engagements. All regional atmospheric properties are acquired from the Laser Environmental Effects Definition and Reference (LEEDR) database created at the Air Force Institute of Technology.

C. LASER AND PLATFORM PARAMETERS

Bearing the combined effect of target and atmospheric parameters in mind, the laser and platform configuration is critical in achieving a successful simulated engagement. The four most important parameters in this regard are the laser beam quality, laser beam wavelength, platform altitude, and laser power output.

1. Laser Beam Quality and Wavelength

As previously discussed, laser beam quality has a significant impact on the beam's irradiance at the target. A beam quality factor of 3 is used in these simulations to model a realistic laser. Atmospheric absorption of laser energy is highly dependent on the laser's frequency. In order to minimize absorption, a lasing wavelength of 1.0642 μm is used in these simulations. While other wavelength "windows" exist that minimize absorption, 1 μm is a commonly used wavelength in a multitude of existing solid-state systems.

1134 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

2. Platform Altitude

The capabilities of the UAV platform are the driving factor in determining the altitude at which the laser will engage the target. Generally, the greater the size and power of a UAV, the greater its maximum operating altitude, or service ceiling, will be. The RQ-7B Shadow, which is the smallest UAV currently used that could potentially carry a laser system, typically operates at an altitude of 2.4 km to 3 km during the day [42]. Conversely, the RQ-4 Global Hawk, which is likely the largest current UAV that could be used in this capacity, has a service ceiling of over 18 km [43].

Since increasing altitude also increases the amount of atmosphere through which the laser beam must propagate, a minimal altitude is ideal for these simulations. Three different altitudes of 1 km, 4 km, and 7 km are considered in this research to provide a reasonable range of values that could accommodate any tactical concerns. While 7 km is certainly not a limit imposed by existing UAV platform capabilities, it is within the upper limit of altitudes that enable engagement dwell times to remain minimal, which is kept within 60 seconds in this research.

3. Laser Power Output

In order to use an airborne platform for these engagements, the laser system must be kept as compact as possible with regard to SWaP design considerations. This is especially significant when the proposed airborne platform is a UAV, which are typically far smaller and less powerful than their manned counterparts or ground-based platforms. Considering the material properties of the proposed targets and the propagation distances of the laser beam, a power output less than 2.5 kW would likely be insufficient to achieve the desired effect, especially at higher altitude and in non-ideal weather conditions.

Fiber lasers are currently a viable solid-state laser option for producing outputs in the kilowatt range while maintaining beam quality and minimizing weight. For example, IPG Photonics, which specializes in producing industrial cutting lasers, manufactures a 1 μm continuous wave ytterbium fiber system with a scalable power output of 1 kW to 10 kW that weighs less than 380 pounds [44]. Such a system would be ideal for providing the necessary power output while minimizing size and weight. Accordingly, this research

1135 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

considers the effects of a 2.5 kW, 5 kW, and 10 kW power output in order to explore a range of powers likely to be mounted onboard a UAV platform.

D. SIMULATION TOOLS

This research relies on a pair of simulation tools developed at renowned defense research institutions. This section will briefly expound on both the inputs and outputs required to incorporate these tools into the simulated engagements.

1. LEEDR

As mentioned, LEEDR is a database of atmospheric conditions that generates regional approximations for the light propagation coefficients discussed in Chapter IV. LEEDR enables the user to control the weather conditions at specified locations using preset values or averages unique to that particular location. For these simulations, regional weather monitoring stations known as "ExPERT" sites in LEEDR will be used. Incheon International Airport is the ExPERT site representative of Seoul, while Kandahar Air Base is the ExPERT site used for the city of Kandahar. With one exception, all weather profiles used are representative of summer weather conditions (July), with the ambient temperature taken as the daily average for that location. The one exception is the precipitous weather profile for Kandahar since southern Afghanistan typically only receives rain during the winter months, which LEEDR bases on average conditions in the month of January. Clear and hazy profiles utilize a relative humidity percentile setting of 50% (i.e., more humid than 50% of measured days, and so represents a typical humidity for that location in January or July). Precipitous profiles utilize a relative humidity percentile setting of 99%. The widely known Hufnagel-Valley model for turbulence [45] was applied to all profiles as well.

Clear weather profiles utilize a Global Aerosol Data Set (GADS) multiplier of 1, which simulates a typical aerosol concentration for that location. The clear weather profiles do not include any cloud or rain effects. Precipitous weather profiles utilize a GADS multiplier of 0.2, the addition of "moderate rain" (a LEEDR setting that corresponds to 12.5 mm per hour), and a cloud layer at 10 km altitude. While a cloud layer at this height is unrealistic, it enables the simulation to demonstrate the effect of rain throughout the path

1136 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

of propagation. Otherwise the extinction effect generated by a cloud layer would completely disrupt a laser beam and prevent target autoignition (this effectively makes any simulations performed at 4 km and 7 km platform altitude under precipitous conditions unrealistic and therefore irrelevant). Finally, hazy weather profiles utilize a GADS multiplier of 3, which simulates high aerosol concentration, and do not include any cloud or rain effects. See Table 3 and Table 4 for a complete listing of settings used to generate the LEEDR weather profiles.

Table 3. Seoul Weather Profile Settings.

Weather	Aerosol Model	Aerosol Multiplier	Rain	Season	Temp.	Relative Humidity Percentile
Clear	GADS	1	-	Summer	Daily Avg.	50%
Precipitation	GADS	0.2	12.5 mm per hour	Summer	Daily Avg.	99%
Haze	GADS	3	-	Summer	Daily Avg.	50%

Table 4. Kandahar Weather Profile Settings.

Weather	Aerosol Model	Aerosol Multiplier	Rain	Season	Temp.	Relative Humidity Percentile
Clear	GADS	1	-	Summer	Daily Avg.	50%
Precipitation	GADS	0.2	12.5 mm per hour	Winter	Daily Avg.	99%
Haze	GADS	3	-	Summer	Daily Avg.	50%

1137 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

2. ANCHOR

Developed at the Naval Postgraduate School, ANCHOR is a scaling code that simulates the effect of atmospheric propagation on a laser beam. Its inputs include the LEEDR weather profile, laser parameters, and platform conditions. Its outputs include the beam waist size and beam irradiance over an array of cross ranges defined by the user. ANCHOR is capable of modeling the effects of extinction, turbulence, and thermal blooming, although the thermal blooming capability is not used in these simulations for the reasons discussed in Chapter IV. For this research, ANCHOR is used as a preliminary simulation for each test case that provides the laser beam parameters at the target prior to and during heat diffusion.

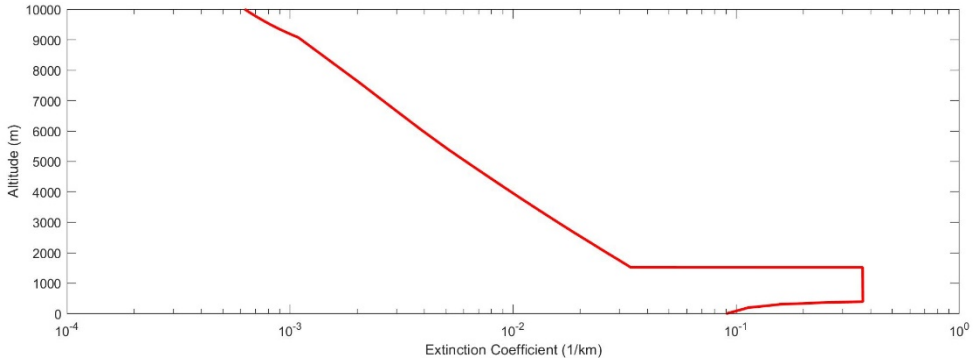
1138 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

VI. RESULTS AND CONCLUSIONS

This chapter discusses the effect that each independent variable has on required dwell times based on results obtained through simulation. The chapter concludes by determining the capabilities of laser systems with different output powers and the potential for mounting them onboard different UAVs based on SWaP requirements.

A. EXTINCTION PROFILES

Climate and weather conditions dramatically alter the atmospheric effects on laser beam propagation. Specifically, the effects of beam extinction are increased from clear to hazy weather, and even further increased when accounting for the presence of precipitation. See Figure 16, Figure 17, and Figure 18 for LEEDR-generated data regarding the extinction coefficient of various weather types in Seoul, South Korea. For reference, see Table 3 and Table 4 for the settings used to generate these figures.



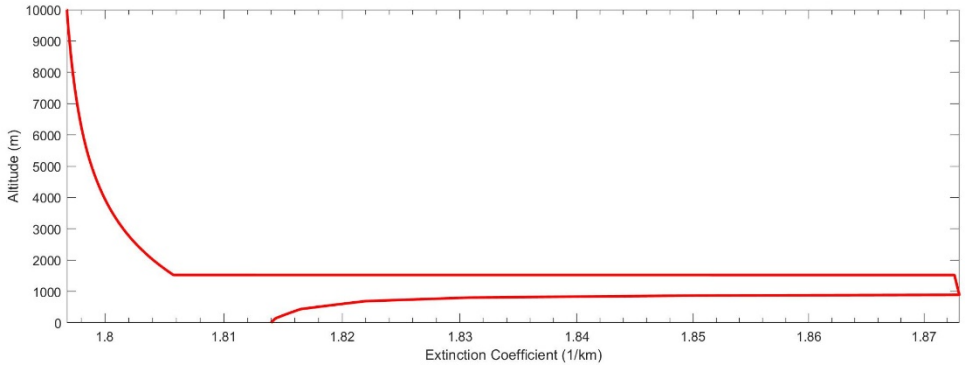


Figure 16. Extinction Coefficient for Clear Seoul Weather Conditions.

1139 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Note the scale used for the extinction coefficient in this figure is linear (unlike the logarithmic scales used Figure 16 and Figure 18).

Figure 17. Extinction Coefficient for Precipitous Seoul Weather Conditions.

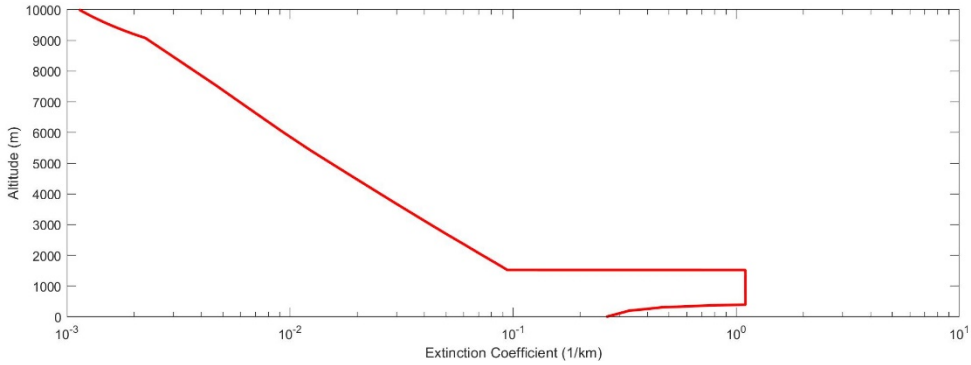

Figure 18. Extinction Coefficient for Hazy Seoul Weather Conditions.

The plots for extinction coefficient share the same general characteristics across both climates and all three weather profiles. From ground-level to an altitude of approximately 1 km (the atmospheric boundary layer), the coefficient value increases. However, just above the boundary layer at approximately 2 km altitude, the coefficient value decreases dramatically and then steadily declines even further with increased altitude. An increase in extinction coefficient value corresponds with a decrease in the amount of laser output power that actually reaches the target in accordance with the Beer-Lambert Law (Equation 6). Of note, the extinction coefficient data for Kandahar, Afghanistan indicates that, for similar weather types, the coefficient value generally remains less than that in Seoul across the platform altitudes simulated. The difference in

1140 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

extinction coefficient profiles can be explained by the relative abundance of atmospheric moisture near Seoul and the absence thereof near Kandahar. The extinction coefficient is inversely related to the surface visibility generated by LEEDR for each profile. Table 5 displays the effects that climate and weather type have on surface visibility.

Table 5. Effects of Climate and Weather on Surface Visibility.

	Seoul, South Korea			Kandahar, Afghanistan		
	Clear	Precipitation	Haze	Clear	Precipitation	Haze
Surface Visibility (km)	23.7	1.64	8.50	33.3	1.64	12.0

The key conclusion to draw with regard to climate type is that, based on the data for these two locations, drier climates will produce more favorable atmospheric conditions for laser beam propagation (not considering the effects of sand storms). This effect is manifested in universally reduced dwell times for targets engaged in an arid desert environment, even when other independent variables are adjusted. In later sections, the Seoul climate profiles will be used to identify the extreme limits under which target autoignition can occur.

B. EFFECT OF WEATHER

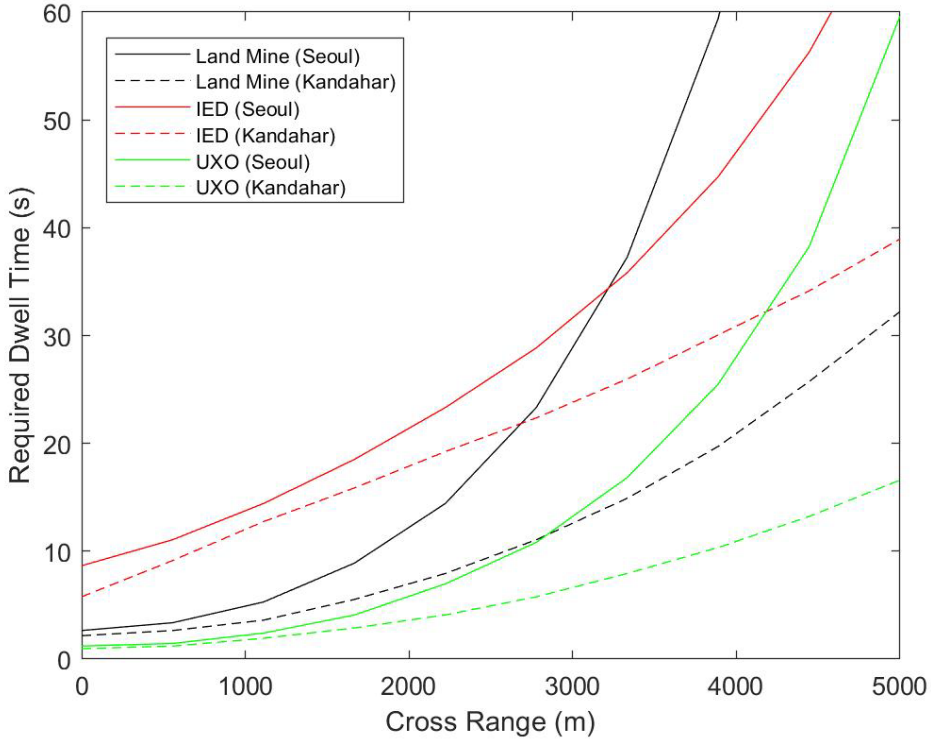
To illustrate the effect of weather type on required dwell time, platform altitude, output power, and target type are kept constant. The comparison in Figure 19 displays data taken from 1 km platform altitude, 2.5 kW output power, and land mine target engagements.

1141 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Note that the plot for hazy Seoul weather conditions stops at a cross range of approximately 1.75 km. This is due to the fact that the simulation is unable to achieve autoignition in the target within 60 seconds of dwell time at greater cross ranges.

Figure 19. Simulation Results for 1 km Platform Altitude, 2.5 kW Output Power, Land Mine Target Engagements.

Predictably, clear weather conditions produce the most favorable dwell times. The reduced presence of atmospheric particles corresponds with reduced beam extinction. Hazy weather conditions produce the next lowest dwell times, since the high concentration of aerosols results in increased beam scattering and absorption. Finally, precipitous weather produces the highest dwell times since the presence of large water droplets effectively extinguishes the beam at greater cross ranges.



This data supports the conclusion that, although required dwell times are severely degraded, a low-power 2.5 kW laser is still capable of successfully engaging ground ordnance across all three weather types simulated. In precipitous conditions, the cross range is reduced to approximately 500 m for a 2.5 kW laser system. However, in clear

1142 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

conditions, the same system can achieve autoignition conditions in the target at a cross range in excess of 5 km.

C. EFFECT OF TARGET TYPE

To illustrate the effect of target type on required dwell times, engagements in clear weather, at 1 km platform altitude, and with 2.5kW output power are considered. See Figure 20 for simulation results.

The plots for land mine and IED targets engaged under similar climate conditions (Seoul) intersect at a cross range of approximately 3.25 km, which indicates that the land mine is a more difficult target to defeat at greater cross ranges under these simulation parameters.

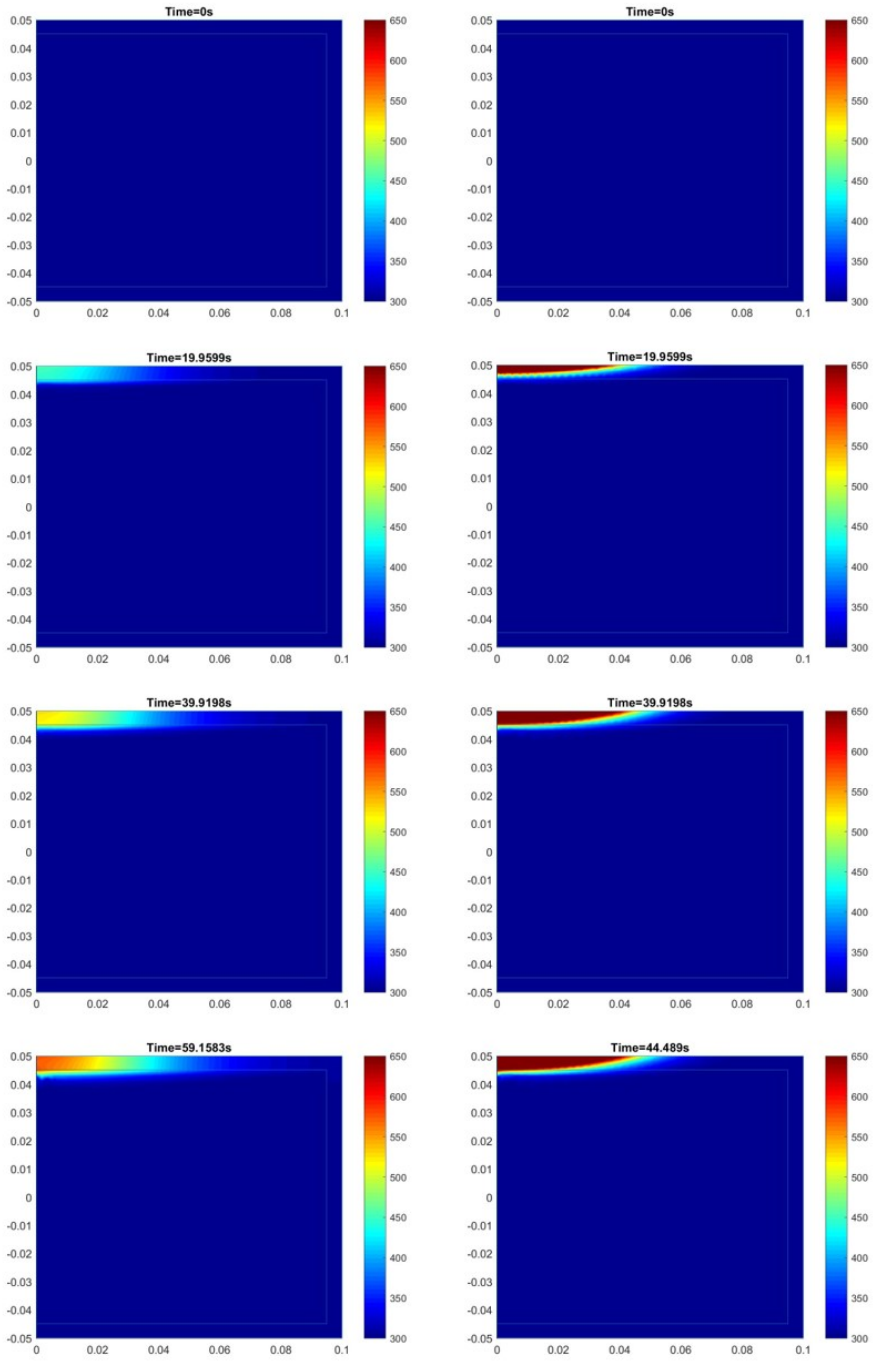


Figure 20. Simulation Results for Clear Weather, 1 km Platform Altitude, 2.5 kW Output Power Engagements.

Outer casing thickness has a significant effect on required dwell time. When comparing the two steel-encased targets, the UXO target profile (2.5 mm of casing) universally produces lower dwell times than the land mine target profile (5 mm of casing).

1143 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Casing material has an even more dramatic effect on dwell times. The dwell times for the IED target profile, with its 5 mm of high density polyethylene casing, increase exponentially with respect to increasing cross range similarly to the steel-encased targets. However, the rate of this exponential increase is noticeably less than that for the steel profiles. Even though the IED target requires greater dwell times at lower cross ranges, the IED target data intersects the land mine target data at a cross range of approximately 3.25 km in Figure 20, after which the IED profile for Seoul actually requires lower dwell times than the land mine profile (also for Seoul). This intersection is indicative of different heating behaviors for both materials as beam irradiance is affected by increases in the propagation path (Figure 21).

1144 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The figures on the left represent heating of a land mine target while the figures on the right represent heating of an IED target. For reference, the axes are in units of meters while the color scale is in units of kelvins. The bottom figure of each target is a depiction of the heating profile immediately prior to autoignition.

Figure 21. Target Cross-sectional Heating in Seoul Climate, Clear Weather, 1 km Platform Altitude, 2.5 kW Output Power, 3.89 km Cross Range Engagements.

1145 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Due to the insulating nature of polyethylene, heat deposited by the laser beam remains relatively local to the beam spot on the surface of the target, where it accumulates and diffuses at a faster rate towards the explosive interface than it does radially outward. However, being a conductive material, steel casing diffuses more heat radially outward from the beam spot. When the beam irradiance is high (i.e., when the spot size is small at shorter cross ranges), the heat diffuses rapidly enough in both directions (towards the explosive interface and radially outward) that the target autoignites. When beam irradiance is low (i.e., when the spot size is larger at longer cross ranges), the radial diffusion prevents enough heat from reaching the explosive interface and autoigniting the RDX in a reasonable amount of time.

Since the melt temperature of high density polyethylene ranges between 383 K and 408 K [46], there is concern that the amount of heat deposited by the laser beam will melt the IED target's outer casing prior to explosive autoignition. However, it is possible to approximate the amount of total energy deposited by the laser beam that would be required to achieve such a state transition. The energy required to melt a material that is being irradiated by a laser beam can be approximated using the equation:

$$E_m \approx H_f \rho \pi w_{tot}^2 l \tag{11}$$

where E_m is the required melt energy, H_f is the heat of fusion (245 kJ/kg for high density polyethylene [46]), w_{tot} is the beam waist size, and l is the material thickness. Conversely, the total energy deposited by the laser beam can be approximated as:

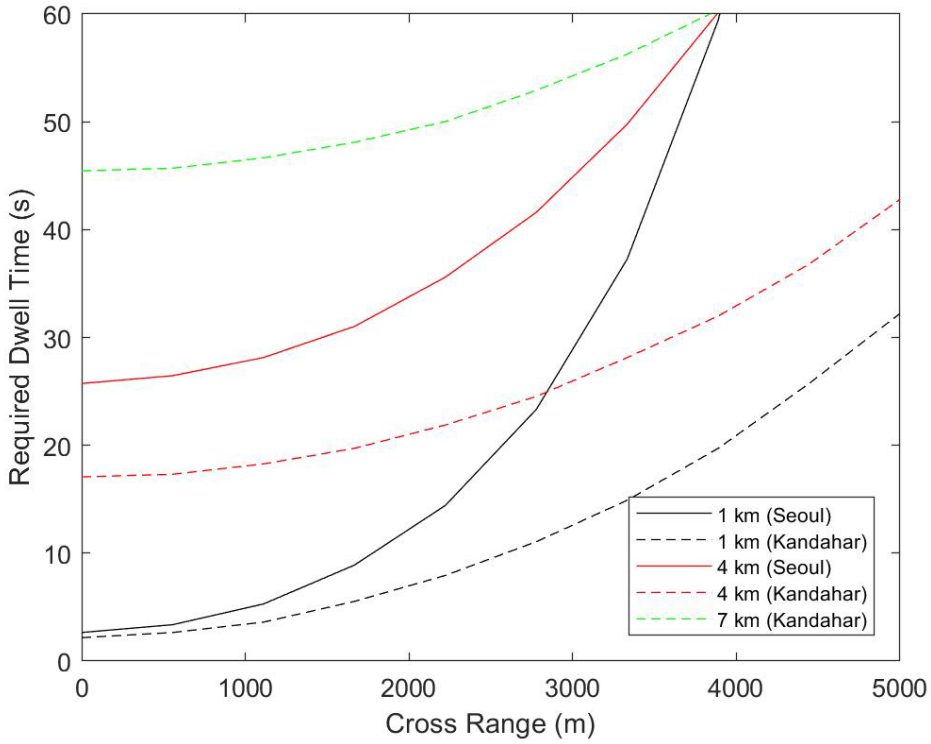
$$E_b \approx I_{pk} \pi w_{tot}^2 t_d (1-R) \tag{12}$$

where E_b is the energy deposited by the beam, I_{pk} is the peak irradiance of the beam, t_d is the required dwell time for autoignition, and R is the reflectivity coefficient of the material. Relating Equation 11 and Equation 12 produces the equation:

$$G \approx \frac{H_f \rho l}{I_{pk} t_d (1-R)} \tag{13}$$

where G is the fraction that relates the energy required to melt the casing material to the total energy deposited by the laser beam. Upon conducting this calculation for a sample of simulations, the percentage is approximated to remain below 10% of the total energy deposited by the laser beam. It is therefore a reasonable assumption to neglect the energy

1146 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING



consumed by melting with regard to the time scales and polyethylene casing thickness modeled in these simulations.

In addition to melting, there is concern over the effect imposed by the removal of polyethylene casing while the target is irradiated (either by burning or gravity). In either case, the removal of mass would reduce the time required for the heat front to diffuse in accordance with the heat diffusion equation mentioned in Chapter III (Equation 1). In the case of burning (high density polyethylene itself has an autoignition temperature of approximately 613 K [46]), the energy released by burning the casing would actually contribute to the heat front diffusion. The ultimate effect of casing removal in either situation would be a reduction in the dwell time required to achieve autoignition in the target. Therefore, by not considering the effect of casing removal in this research, the simulation results are likely to be conservative (i.e., higher dwell times) than those that would be achieved through experimentation. Having established that the land mine and IED target types are the most difficult with which to achieve autoignition conditions, they are used as the standards by which to establish the requirements of a laser system intended to defeat ground ordnance.

D. EFFECT OF PLATFORM ALTITUDE

Simulated engagements performed in clear weather, with 2.5 kW output power, and against land mine targets are used to compare the effect of platform altitude on required dwell time (Figure 22).

1147 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The plot for an engagement in Seoul at 7 km platform altitude is not available since the simulated laser beam is unable to achieve autoignition conditions in the target within 60 seconds of dwell time.

Figure 22. Simulation Results for Clear Weather, 2.5 kW Output Power, Land Mine Target Engagements.

There is a universally strong relationship between platform altitude and the required dwell time to achieve autoignition conditions. This can be explained by the increased effects of scattering, absorption, and turbulence as the propagation path of the laser beam increases. Although lower altitudes result in reduced engagement dwell times, they are also disadvantageous for UAV operations. An aircraft operating at low altitude is more vulnerable to anti-aircraft defenses, and relatively slow-moving UAVs are particularly vulnerable. Since low-level cloud layers typically exist below 2 km altitude [47], the only tactical reason for a UAV to operate below this altitude would be the presence of rain clouds (hence why precipitous weather simulations are relevant at 1 km altitude, but not 4 km or 7 km) or in overcast conditions. However, conducting engagements at high altitude places a tax on the laser system's requirements. Of note, the plots for the 1 km platform altitude and 4 km platform altitude engagements in Seoul converge at a cross range of

1148 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

approximately 4 km. This can be attributed to the effect of increased extinction coefficient in the atmospheric boundary layer. While the simulation performed at 1 km platform altitude must propagate almost the entire distance with a very large coefficient value, the simulation performed at 4 km platform altitude only propagates through the boundary layer for approximately half of the distance to the target.

E. EFFECT OF OUTPUT POWER

Engagements performed in clear weather, at 1 km platform altitude, and against land mine targets are used to determine the effect of laser output power on required dwell times. See Figure 23 for a visual comparison of the data.

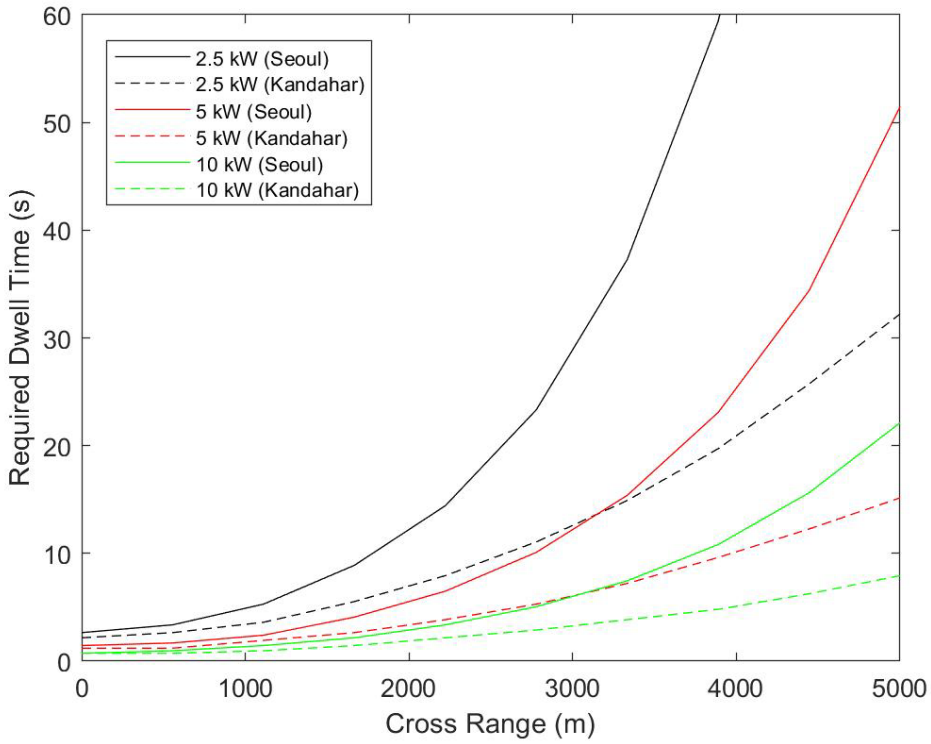


Figure 23. Simulation Results for Clear Weather, 1 km Platform Altitude, Land Mine Target Engagements.

As expected, laser output power plays a significant role in determining the required dwell time. Greater output power means that more energy is deposited at the surface of the

1149 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

target and consequentially increases the diffusion speed of the heat front through the outer casing. Of all the independent variables tested in this research, laser output power is the most significant with regard to designing a system capable of achieving target autoignition across all conditions.

As identified in previous sections of this chapter, engagements that occur in a temperate climate (Seoul) are non-ideal relative to those that occur in a drier climate (Kandahar). Additionally, depending on the platform altitude, precipitous and hazy weather are the most disruptive weather conditions regarding laser beam propagation. Finally, land mine and IED target types are the most difficult to defeat. These conclusions enable identification of the maximum capabilities of the three simulated output powers. A temperate climate with precipitous weather at 1 km platform altitude is the most non-ideal situation under which a 2.5 kW output power can achieve autoignition in the two most difficult target types (Figure 24).

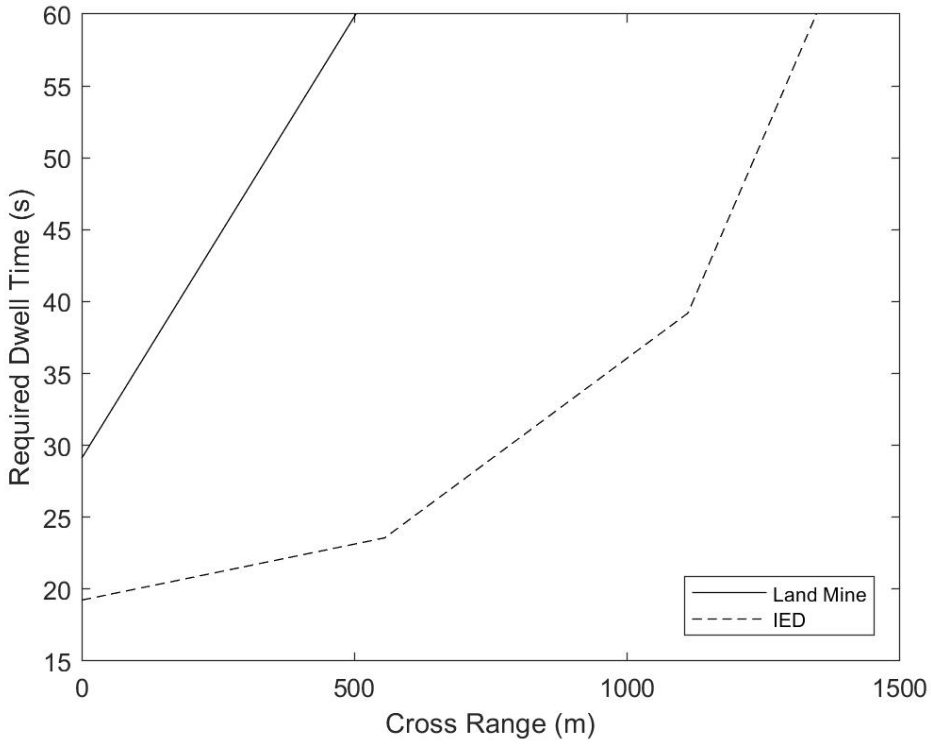

Figure 24. Simulation Results for a Seoul Climate, Precipitous Weather, 1 km Platform Altitude, 2.5 kW Output Power Engagement.

1150 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Increasing the output power of the laser to 5 kW enables target autoignition at a platform altitude of 4 km in hazy weather conditions (Figure 25).

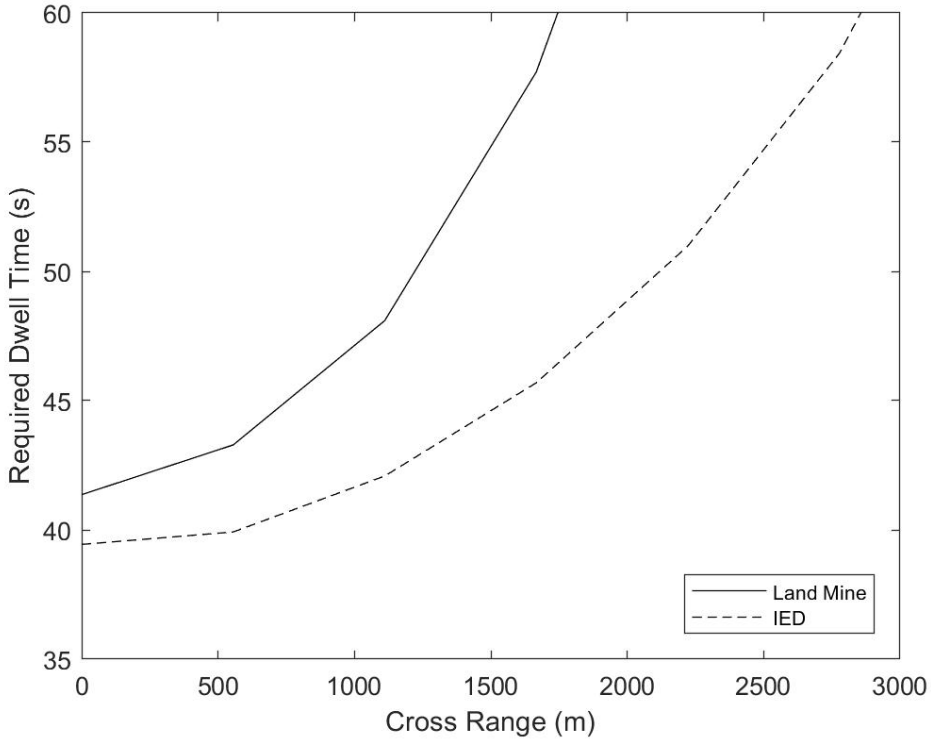

Figure 25. Simulation Results for a Seoul Climate, Hazy Weather, 4 km Platform Altitude, 5 kW Output Power Engagement.

1151 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Finally, the maximum simulated output power of 10 kW enables target defeat at a platform altitude of 7 km in hazy weather conditions (Figure 26).

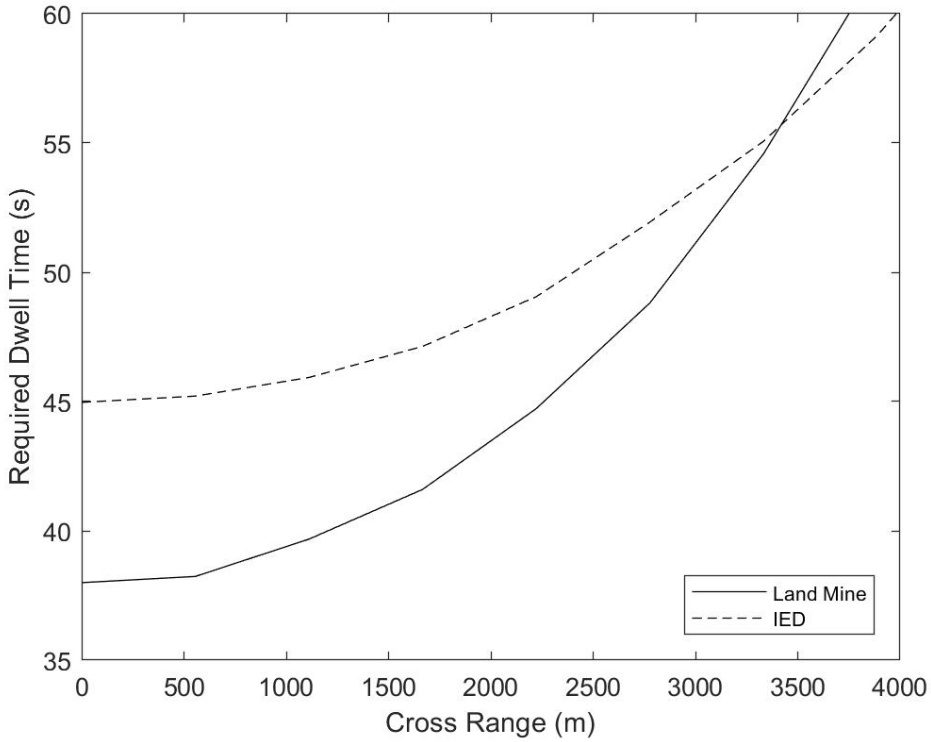

Figure 26. Simulation Results for a Seoul Climate, Hazy Weather, 7 km Platform Altitude, 10 kW Output Power Engagement.

F. CONCLUSIONS

It is feasible to engage and defeat ground ordnance using an airborne solid-state laser. At a platform altitude of 1 km, these simulations indicate that all three tested output powers are capable of achieving autoignition conditions in both climates, across all weather profiles, and against each target type. The most restrictive variable is weather, which effectively limits the platform altitude to the cloud layer during precipitous weather. Additionally, in order to defeat all three target types in clear or hazy weather and in either climate, the minimum required output power increases to 5 kW for 4 km platform altitude engagements and 10 kW for 7 km platform altitude engagements.

1152 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The concept of using UAV-mounted solid-state lasers to defeat ground ordnance bears utility. As an example, the IPG Photonics YLS-3000-SM system produces a similar beam to the one simulated in this research with an output power of 10 kW and contained in a compact 0.95 m^3 package [48]. A similar model listed by the company weighs less than 380 pounds and has a published wall-plug efficiency greater than 50% [44]. This means that the system could be operated with a power source that outputs an average of 20 kW. While these SWaP requirements are too large for smaller UAVs such as the RQ-7B Shadow, they do not supersede the capabilities of mid-size UAVs such as the MQ-1C Gray Eagle, which has a payload capacity of 1,075 pounds [49]. This would enable current U.S. Army forces to maintain a responsive airborne ordnance-clearing asset at the division echelon.

There are many opportunities for expansion of this research. The diffusion of heat to achieve autoignition is just one defeat mechanism particular to a specific target type. Different target types with other defeat mechanisms should be studied in order to grasp the full utility of airborne laser systems. Additionally, expanding the selection of platforms beyond UAVs could create possibilities with regard to increased SWaP availability. Rotary and fixed-wing aircraft could theoretically carry laser systems with greater output power, which in turn increases the feasibility of defeating different target types. As solid-state laser systems continue to become more compact and powerful, it is highly likely that airborne laser weapons will become a fixture on future battlefields.

13. ABSTRACT (maximum 200 words)

Explosive devices present a significant threat to civilian populations and are a severe counter-mobility obstacle for ground forces. With the proliferation of improvised explosive devices into potential U.S. military operating areas, a safer and more efficient method for eliminating the threat is required. U.S. Army forces operating at the brigade and above echelons are generally supported with a variety of unmanned aerial vehicle (UAV) airframes that are capable of conducting reconnaissance and surveillance. These UAVs are faster and more responsive to reports of ground-based explosive devices than explosive ordnance disposal (EOD) teams or route clearance patrols. If UAVs were equipped with a system capable of disarming or destroying explosive devices, the stress on EOD assets would be mitigated and the delaying effect of said explosives on ground forces would be reduced. This research explores the feasibility and utility of using a high-energy laser mounted onboard a UAV platform to defeat ground-based explosive devices. Specifically, this research defines an array of potential targets, characterizes the atmospheric effects in varied weather conditions and climates on such a laser system, and contrasts the size, weight, and power requirements of such a system with the operating capabilities of existing UAV platforms.

ABSTRACT

Explosive devices present a significant threat to civilian populations and are a severe counter-mobility obstacle for ground forces. With the proliferation of improvised explosive devices into potential U.S. military operating areas, a safer and more efficient method for eliminating the threat is required. U.S. Army forces operating at the brigade and above echelons are generally supported with a variety of unmanned aerial vehicle (UAV) airframes that are capable of conducting reconnaissance and surveillance. These UAVs are faster and more responsive to reports of ground-based explosive devices than explosive ordnance disposal (EOD) teams or route clearance patrols. If UAVs were equipped with a system capable of disarming or destroying explosive devices, the stress on EOD assets would be mitigated and the delaying effect of said explosives on ground forces would be reduced. This research explores the feasibility and utility of using a high-energy laser mounted onboard a UAV platform to defeat ground-based explosive devices. Specifically, this research defines an array of potential targets, characterizes the atmospheric effects in varied weather conditions and climates on such a laser system, and contrasts the size, weight, and power requirements of such a system with the operating capabilities of existing UAV platforms.

ACKNOWLEDGMENTS

I'd like to thank my advisors, Professors Keith Cohn and Joseph Blau, for their vast knowledge, assistance, advice, and patience throughout this research. There wasn't a problem that they couldn't help with, and they were always a step ahead of me on this project.

To my wife, Erin, who is my greatest friend, supporter, and editor. I couldn't imagine a better partner in life. Thank you for always helping me to keep it in perspective and not sweat the little things.

Lastly, to my two beautiful daughters, Ava and Louise. You both remind me every day how blessed I am to be a father. Each day is filled with wonderment as your mother and I watch you grow up (but not too fast)!

I. INTRODUCTION

Explosive devices are among the most effective obstacles to ground maneuver in combat. Properly placed, these devices can inflict casualties, deny terrain, steal operational tempo, and threaten civilian populations. According to figures in 2008, approximately 70% of the then 4,163 U.S. combat deaths in Iraq since the start of the war in 2003 were due to roadside bombs [1]. Their proliferation and successes over the past decade ensure that improvised explosive devices (IEDs), land mines, and unexploded ordnance (UXO) remain a threat in future U.S. Army operating environments.

A. GROUND ORDNANCE THREATS

Relative to the weapons used in modern armed forces, IEDs are cheaply produced and readily available to insurgent or terrorist organizations. A bomb maker might expend less than $100 for an IED capable of destroying a light vehicle as compared to more than $100,000 for a conventional U.S. precision munition [2]. Simply put, organizations that employ IEDs are obtaining a comparable tactical effect for a fraction of what the U.S. government pays per application, and they are doing so without the billions of dollars poured into the acquisition and production of new weapon systems.

Land mines and UXO have a detrimental effect on both combat operations and civilian populations. Like IEDs, these munitions excel in the counter-mobility role against ground forces. However, once they have been bypassed, land mines and UXO still present a significant threat to civilian populations in the vicinity. As of 2003, Soviet land mines from the war in Afghanistan that ended in 1989 still inflicted approximately 300 civilian casualties per month [3]. Unfortunately, even modern armed forces continue to leave behind these dangerous explosives due to limited disposal assets and competing priorities. Apart from the broader humanitarian argument, this threat presents a more immediate challenge to the U.S. Army if the mission specifically entails protection of the civilian population.

1184 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

B. CURRENT REMOVAL METHODS

Ground-based explosive devices are undoubtedly a problem that the U.S. Army needs to solve safely, effectively, and cheaply in order to be successful on future battlefields. Current removal methods rely on the use of highly specialized units and equipment that may not always be available and are expensive to field. Directed energy is a potential solution to the threat posed by these devices. The Department of Defense recognized the utility of lasers on the battlefield as far back as the 1960s [2] and has since committed funding to multiple projects as a means of combatting a variety of threats to friendly forces.

C. POTENTIAL ADVANTAGES OF DIRECTED ENERGY EMPLOYMENT

In 2004 the U.S. Army demonstrated that in-flight mortar rounds can be destroyed using a ground-based high energy laser. The Mobile Tactical High Energy Laser (MTHEL) destroyed seven medium in-flight mortars during testing, which included a three-round salvo [4]. In 2008 the U.S. Special Operations Command mounted a 100 kW laser on an AC-130 gunship and dubbed it the Advanced Tactical Laser (ATL). The ATL was intended to function as a direct fire weapon against ground targets, which included a remotely controlled vehicle in one particularly successful test [5]. Finally, in 2010 the U.S. Air Force succeeded in destroying an in-flight ballistic missile using the Airborne Laser (ABL), a megawatt-class laser mounted inside a Boeing 747 [5] (Figure 1).

1185 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 1. YAL-1A Airborne Laser. Source: [6].

Although the MTHEL, ATL, and ABL were successful during testing in ideal conditions, all three projects were cancelled for the same general reasons. Each system utilized a large chemical laser that, aside from the massive size (the MTHEL required several oversized trailers to move across the battlefield [5]), required the transportation, storage, and handling of dangerous and expensive chemicals. Additionally, each project was built on the assumption that the laser would be in the right location at the right time to strike a fast moving target. In the case of the ABL, five to seven Boeing 747s would have to maintain a presence near a missile launch site for a successful interdiction [5]. Such a quantity of large, slow aircraft loitering over enemy controlled territory would be an irresistibly attractive target. In order for directed energy to be successful in tactical engagements, lasers must be smaller, logistically simple, and mobile.

This study models the use of solid-state lasers mounted on unmanned aerial vehicles (UAVs) against surface-laid ground ordnance. Solid-state lasers operate by electricity instead of chemical reactions and are generally much smaller than chemical lasers. Current solid-state lasers also produce much less optical output power than their chemical relatives, but this may be offset by the intended application. While the MTHEL, ATL, and ABL required high irradiance over a short dwell time to be successful, a solid-state laser that targets ground ordnance has the luxury of an extended engagement period

1186 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

since IEDs, land mines, and UXO don't move. Additionally, the explosives used in these potential targets self-ignite at temperatures of a few hundred kelvins; this is considerably lower than the temperatures needed for other target types (e.g., to melt through missile casings). Thus, the irradiance, and consequentially the output power, of the laser can be reduced while still achieving the desired effect.

UAVs are ideal platforms for destroying ground ordnance with solid-state lasers. Currently, a brigade combat team (BCT) in the U.S. Army fields four RQ-7B Shadow UAVs that are intended to provide 24-hour geographic coverage for that BCT's area of operations. The availability of UAVs only increases at each higher echelon, with the MQ-1C Gray Eagle (Figure 2) fielded at the division-level. This means that there is a persistent and flexible UAV presence within every area of operations that could potentially put a laser at the right location and time to be effective against the ground ordnance threat. Additionally, UAVs have a large stand-off distance from ground targets that eliminates the need to put soldiers or expensive equipment within the blast radius of said ground ordnance. The challenge for using UAVs in this intended application lies in the fact that all of these platforms have limited capacity for the size, weight, and power (SWaP) requirements inherent to solid-state lasers.

1187 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Aside from the engineering challenges associated with mounting lasers on UAVs, an air-to-ground directed energy system must consider atmospheric propagation effects such as diffraction, scattering, absorption, and turbulence [2]. Consequentially, the required beam output power must be designed to overcome these effects and cross the lethal fluence threshold at the target.

D. OVERVIEW OF STUDY

This study identifies the energetic compounds used in common IEDs, surface-laid land mines, and pieces of UXO in order to estimate the lethal fluence needed for these compounds. Based on this information, the study then estimates the laser power needed to achieve the lethal fluences over acceptable dwell times for various atmospheric conditions. Finally, the study discusses the feasibility of using solid-state lasers against ground ordnance based upon SWaP considerations and UAV platform availability.

II. OVERVIEW OF DIRECTED ENERGY WEAPONS

As it is applied to weaponry, the term “directed energy” can have a multitude of meanings. For example, the deposition of energy on a target can be accomplished through the use of microwaves, particle beams, or high energy lasers (HELs). However, for directed energy weapons to be effective, the delivery method, target parameters, platform allowances, and propagation medium must be such that the desired result on the target is achieved. HELs are currently a highly active subject of study for defense applications and will be the focus for this research due to their relative advantages over other types of directed energy weapons.

A. HISTORY

The development of HELs as weapons began almost immediately following the invention of the first laser in 1960. The Soviet Union started researching the feasibility of HELs defeating intercontinental ballistic missiles during their reentry phase in 1965, going so far as establishing a town of 20,000 people at Raduga to conduct research and testing [8]. The United States followed when Ed Gerry created a gas dynamic CO2 laser with an output power of 100 kW in 1968 [8]. Each branch of the armed forces began funding their own projects tailored for their specific requirements.

The next major advancement came from the U.S. Navy with the creation of the Navy ARPA Chemical Laser (NACL), which was a multi-hundred kilowatt-class chemical laser. The NACL successfully destroyed tube-launched optically-tracked wire-guided (TOW) missiles in-flight in 1978 and led to the development of the Mid-IR Advanced Chemical Laser (MIRACL) in 1980, which was the world’s first megawatt-class laser [9]. However, chemical lasers are not ideal for ship-based applications due to the fuels required and exhaust they create. Additionally, the less-than-ideal output wavelength produced by these lasers were prone to atmospheric absorption, which resulted in decreased irradiance at the target and thermal blooming. These factors contributed to a hiatus in Navy HEL design until a suitable alternative with comparable power outputs could be developed. In 2014, the 30 kW AN/SEQ-3 Laser Weapon System (LaWS) (Figure 3) was installed on

1190 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the USS *Ponce* and successfully demonstrated the ability to destroy small boats and UAVs [10]. The LaWS is a solid-state system that circumvents the challenges of chemical lasers at the expense of an output that is lower by at least an order of magnitude.

Figure 3. LaWS Onboard the USS *Ponce*. Source: [11].

The U.S. Air Force created the Airborne Laser Lab (ALL) with a 100 kW class gas dynamic laser mounted in a KC-135 aircraft, which succeeded in destroying AIM-9 missiles and BQM-34 drones during testing in 1983 [8]. Due to the relatively low electrical power requirements of chemical lasers, this type of system was the basis of the Space Based Laser (SBL) program that began in 1989 with the purpose of defeating ICBMs in their boost phase. The program intended to conduct a successful demonstration by 2012 [9], but was cancelled in 1991 [8]. Building on the successes of the ALL and prompted by the cancellation of the SBL, the Air Force began work on the ABL program in 1994, which incorporated a megawatt class laser in a Boeing 747 [8]. As mentioned in the previous chapter, the ABL was successful during testing in its intended purpose of destroying ballistic missiles in the boost phase, but the requirement of putting the laser within range of a target and program costs led to its cancellation.

1191 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Meanwhile, the U.S. Army took an interest in using ground-based HELs to counter indirect fire. Research for the Tactical High Energy Laser (THEL) began in 1996 as a joint venture between the United States and Israel as a means to interdict Katyusha rockets [9]. The THEL achieved successes in testing against rockets in 2000 and against mortar rounds in 2004, but proved too expensive and unwieldy on the battlefield. The THEL and its offshoot, the MTHEL, were cancelled due to a lack of available funding. Although the Army lost interest in the THEL and MTHEL, it did not lose interest in ground-based HEL applications and by March 2003 deployed the Zeus HMMWV Laser Ordnance Neutralization System (Figure 4) to Afghanistan to assist with UXO removal [12]. That version of the Zeus incorporated a 500 W neodymium yttrium aluminum garnet (Nd:YAG) solid-state laser [9] with an effective range of 300 meters [12]. During its six-month deployment to Bagram Air Field, the Zeus negated over 200 pieces UXO, including a record-breaking 51 pieces of UXO in less than 100 minutes [12]. The performance of the Zeus demonstrated the feasibility of using a HEL to destroy ground ordnance.

Figure 4. Zeus HMMWV Laser Ordnance Neutralization System. Source: [13].

1192 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Nearly 60 years of HEL design and testing revealed several lessons regarding their use as weapons. Although chemical and gas lasers are capable of achieving higher output powers at relatively better efficiencies, they are also unwieldy, if not downright dangerous to the user in battlefield applications. Solid-state lasers are currently receiving the most attention due to innovations that have increased their power output, their safer electrical "fuel," and their ideal wavelength for atmospheric propagation. This research will focus primarily on solid-state systems due to these reasons, especially considering the projected application of using them onboard UAVs. As the Zeus device demonstrated, only modest output power is needed to affect the desired result against ground ordnance.

B. ADVANTAGES AND DISADVANTAGES

Solid-state HELs have numerous advantages when compared to conventional ballistic weapons. Perhaps the most significant is that the beam propagates at the speed of light. The next major advantage of HELs is the cost per engagement associated with using the weapon. Ballistic munitions are expensive and only available in limited quantities; armored vehicles, aircraft, and ships can only carry a finite number of rounds, bombs, or missiles. On the other hand, lasers only cost the fuel required to generate electricity for each engagement; a typical cost of less than a dollar compared to thousands of dollars for conventional munitions. Finally, HELs can generally outrange conventional line-of-sight munitions if the laser is designed to overcome the effects of scattering and absorption that lead to beam extinction.

Solid-state HELs do come with some inherent disadvantages that have so far prevented their widespread deployment. Compared to ballistic munitions and chemical or gas lasers, solid-state HELs are inefficient. The typical "wall-plug" efficiency for solid-state systems is on the order of 20% to 30%, which necessitates an electrical power source capable of providing hundreds of kilowatts for each engagement. This inefficiency leads to heat generation in the lasing medium that must be actively removed. Cooling systems that can effectively dissipate the heat add additional power and weight requirements. Additionally, any HEL system is more susceptible to atmospheric effects, such as precipitation and haze, than conventional ballistic munitions. Since the defeat mechanism

1193 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

employed by HELs typically involves heating of the target, a laser must also overcome the energy loss resulting from light reflected by the target's surface.

Considering the objective of this research, airborne HELs are an attractive option for defeating explosive devices. If explosive ordnance disposal (EOD) personnel decide that a device can be rendered ineffective in-situ, there are a variety of methods available that include disruptors, anti-munition rifles, de-armers, explosives, fuze removal, or fuze immunization [14]. All of these options require deployment of EOD teams and potentially place these specially trained personnel at risk (Figure 5). Simply the loss of time incurred by friendly forces is often enough to justify the emplacement of explosive devices by the enemy. By requiring friendly forces to adjust from a proactive posture to a reactive one, an enemy that employs these devices steals the tactical initiative. Conversely, HELs (particularly airborne systems) enable the discoverer of an explosive device to act expeditiously and with pinpoint precision. Barring prohibitive weather conditions, UAVs continuously occupy the airspace of a U.S. Army unit's area of operations. The operational cost in time incurred by a friendly unit that encounters an explosive device could potentially be cut from hours (waiting on an EOD team or combat engineers to arrive) to minutes (the time it takes to direct an already airborne clearance asset to the location). This is not to say that using airborne HELs to dispose of explosive devices completely negates the need to have EOD assets available; weather occasionally grounds UAVs, disposing of a device in-situ is not always a possibility, and it is likely infeasible to use a HEL to defeat buried devices. However, it does provide another option for ground commanders to leverage based on the merits of the tactical situation.

C. PROJECTED APPLICATIONS

HEL systems have demonstrated success in testing and limited field deployments, and the next generation of these weapons are currently in the design phase. The Navy established their Directed Energy Program Office within the Program Executive Office for Integrated Warfare Systems in August 2016 [16]. In a February 2017 Federal Business Opportunities posting, this office requested industry capabilities for a new program that consists of a 60 kW HEL with counter-ISR dazzling capability and is capable of operating on an Arleigh Burke-class guided missile destroyer [16]. The Air Force is currently funding a demonstration called SHIELD, which intends to integrate a solid-state HEL with an output power in the tens of kilowatts range on a fighter-size aircraft by 2020 [17]. The Army is investing in its High Energy Laser Mobile Demonstrator, a ground-based system primarily intended to counter indirect fire and UAVs and is capable of being transported by a relatively small armored vehicle such as a Stryker personnel carrier [18]. All of these projects underline the increased interest in HEL weapons, particularly solid-state systems, and the great advances that have been made in HELs since the first laser was invented in 1960.

1195 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

III. CHARACTERIZATION OF HIGH EXPLOSIVE TARGETS

Land mines, UXO, IEDs, and most other high explosive devices share the same basic components and principles of operation. It is this similarity that enables a single clearing system, such as a HEL, to be effective against a wide range of potential threats. Accordingly, three different explosive devices serve as target profiles for this research: the TM-83 anti-vehicle (AV) land mine, the PTAB-2.5M high explosive anti-tank (HEAT) sub-munition, and a Composition C-4 based IED. These devices were selected due to how well they characterize each category of munition (surface-laid land mine, UXO, and IED, respectively), current usage, and variety in construction and materials. This chapter will describe the fundamental components of high explosive devices and will detail the defeat mechanism selected for their removal using a HEL.

A. COMPOSITION

Explosive devices generally consist of four basic components; the detonator, the booster charge, the main charge, and the casing. The detonator is the component that triggers a detonation and can come in many forms. Conventional munitions such as bombs and artillery shells that are commonly found as UXO contain a fuze or a timer for this purpose. Land mines and IEDs make use of switches, sensors, wired detonators, or wireless receivers (Figure 6). Regardless of the form, the detonator is ultimately what initiates an explosive reaction in the booster charge.

1196 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 6. IEDs Captured in Afghanistan with Detonators Mounted on Top. Source: [19].

Booster charges are an intermediary material between the detonator and the main charge. Detonators usually do not provide enough energy to trigger an explosive reaction in the most common types of high explosives, so a less stable explosive is used to create a shock wave that will detonate the main charge. The main charge is what gives a device its explosive power and is usually the largest internal component (Figure 7). Common military-grade explosives used for main charges include trinitrotoluene (TNT), research department explosive (RDX), and high melting explosive (HMX). Perhaps the most commonly used combination of these explosives is Composition B-3, which is a 60% RDX and 40% TNT mixture [20].

1197 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

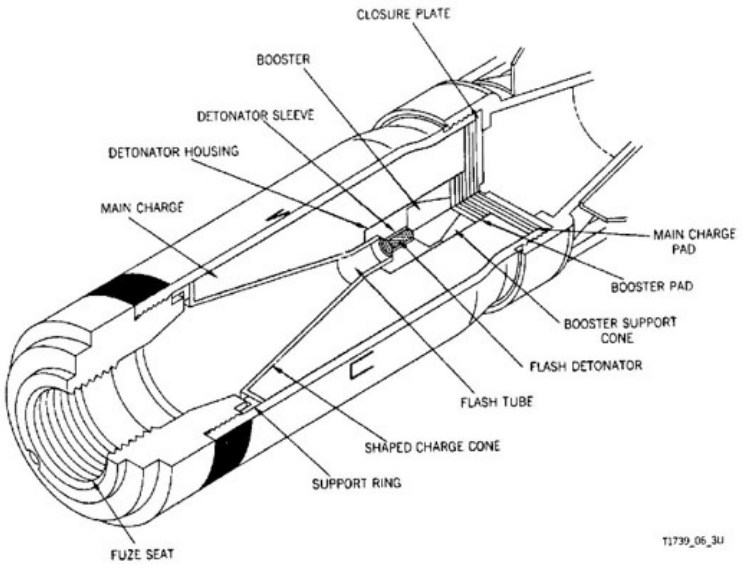

Figure 7. Cross-sectional Diagram of a PTAB-2.5M HEAT Sub-munition Depicting Booster and Main Charges. Source: [21].

The final basic component found in most explosive devices is the casing. The number of combinations of materials, shapes, and fragmentation patterns found in casings is effectively limitless. Metal casings provide durability and double as shrapnel when the device detonates, but are easier to detect with the magnetic scanners commonly employed by clearing assets. Conversely, plastic casings are difficult to detect, but require more care during handling and must be filled with some form of shrapnel to maximize effectiveness. Of particular note is the modern use of the explosively formed penetrator (EFP), which is a circular concave piece of malleable metal (usually copper) that is mounted over the main charge. Upon detonation, the explosive forces reshape the metal into a molten dart-like projectile capable of penetrating most types of armor. The TM-83 AV land mine is an example of a device that produces an EFP (Figure 8).

1198 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

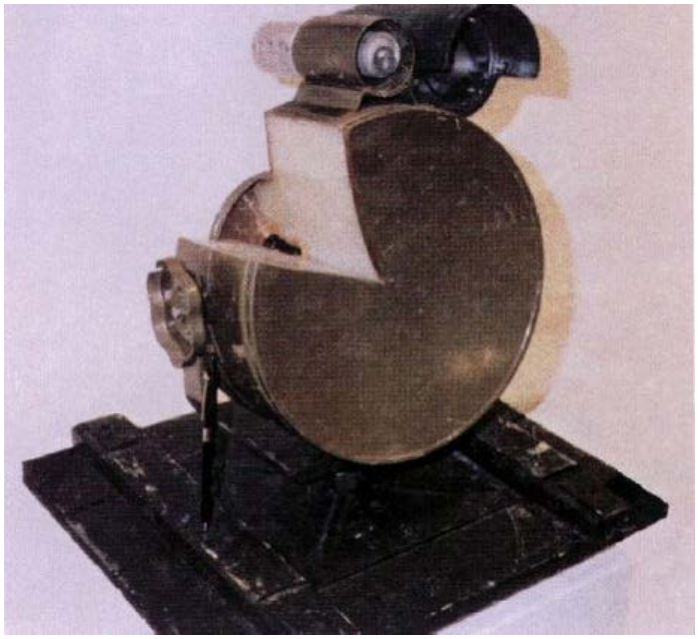

Figure 8. TM-83 AV Land Mine with Triangular Cutout Exposing Main Charge. Source: [22].

B. HIGH EXPLOSIVE PROPERTIES

The potential energy of an explosive material is analogous to a boulder resting on the edge of a cliff [23]. Initially, a great deal of energy is expended to move the boulder to this position. For explosives, this is referred to as the heat of formation. Once the boulder is at the edge, only a slight nudge is required to push it over and expend the high potential energy stored within. Accordingly, this nudge is known as the activation energy. The relatively rapid expenditure of energy during this detonation is what differentiates explosives from other high-energy materials such as wood, coal, or oil. In the case of coal versus HMX, the power output is a difference of nine orders of magnitude [23].

In this research, the "nudge" is the defeat mechanism used to destroy the designated targets. The HEL acts as an energy pump by depositing a portion of its energy in the form of heat on the surface of the target (the rest of its energy is reflected depending on the surface material). As the HEL deposits more energy over time, the temperature of the casing rises as heat diffuses through it and ultimately reaches the main charge contained

1199 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

within. The heat transfer in both the casing and main charge is easily modeled with the well-known heat diffusion equation:

$$\rho c_p \frac{\partial T}{\partial t} = \nabla \cdot (\kappa \nabla T) \tag{1}$$

where ρ is the density of the casing or main charge, c_p is the specific heat capacity, T is the temperature, and κ is the thermal conductivity. Once the interface between the casing and main charge reaches an explosive property known as the autoignition temperature, the main charge will begin expending its potential energy in a manner similar to the falling boulder. While this mechanism will not produce a full detonation, it will render the explosive device ineffective by forcing the main charge to deflagrate [24]. This removal method can actually be more favorable than full detonation if the explosive device is located in close proximity to valuable infrastructure or populated areas.

C. EFFECT OF HEATING

As heat deposited by the laser beam accumulates at the interface between the casing and the main charge, the explosive material will undergo a chemical reaction and release its stored potential energy in the form of additional heat. The rate at which the explosive releases heat as it undergoes the chemical reaction is known as the thermal rate constant. While the constant is initially a relatively small value, it will grow exponentially as the heat deposited by the HEL combines with the accumulating heat emitted by the explosive. The empirical Arrhenius Law is probably the oldest yet best-known model for expressing this thermal rate constant *k(T)* [25]:

$$k(T) = Ae^{-\frac{E}{k_B T}} \tag{2}$$

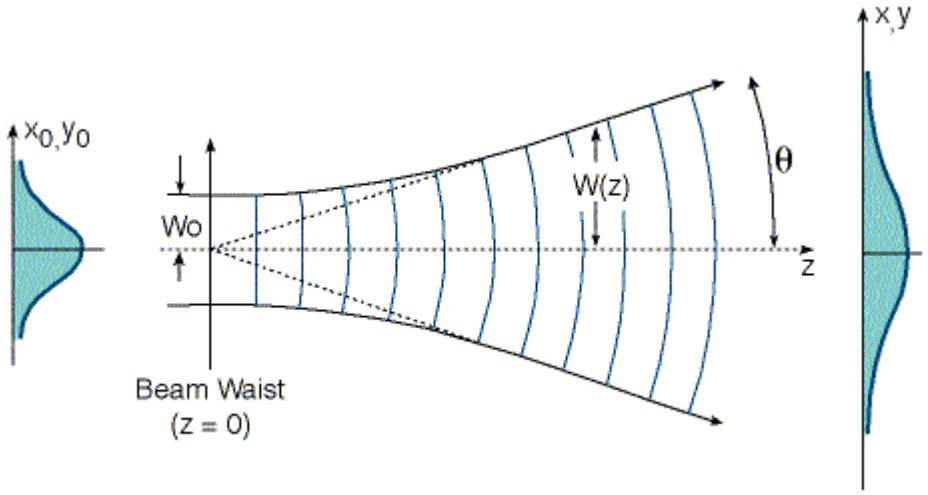
where A is a pre-exponential constant, E is the activation energy, k_B is the Boltzmann constant, and T is the temperature of the explosive material. The pre-exponential constant is unique to a given chemical reaction and is often determined experimentally with units similar to the thermal rate constant (with magnitude typically on the order of 10^{10}) [26]. When the temperature is low, this pre-exponential factor is suppressed. However, as the temperature of the explosive rises relative to its activation energy, the extremely large pre-exponential factor causes the thermal rate constant to increase dramatically. The complete

1200 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

model for predicting heat transfer in an explosive material is a combination of both the heat diffusion equation (Equation 1) and the Arrhenius Law (Equation 2) and appears as:

$$\rho c_p \frac{\partial T}{\partial t} = \nabla \cdot (\kappa \nabla T) + \rho Q Z e^{-\frac{E}{k_B T}} \tag{3}$$

where Q is the heat of decomposition and Z is the characteristic reaction rate of the explosive [27]. The product of the explosive's density, heat of decomposition, and characteristic reaction rate is the pre-exponential constant A annotated in Equation 2. The Arrhenius term acts as a heat source in the heat diffusion equation. Once the temperature T reaches the autoignition temperature, the Arrhenius term dominates and acts as a "positive feedback loop," producing a "run-away" reaction. The predicted autoignition temperature for Composition B-3 is approximately 800-K [20], while the predicted value for Composition C-4 is approximately 650-K [20].



1201 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

IV. LASER BEAM PROPAGATION THROUGH THE ATMOSPHERE

The environment through which a laser beam propagates can dramatically affect the beam's properties from origin to termination. The Earth's atmosphere is full of molecules and particles that can influence a laser beam, and this fact must be accounted for in any system that intends to propagate over a meaningful distance. This chapter will describe those effects as well as their impact on an airborne laser system engaging ground-based targets.

A. VACUUM PROPAGATION

Before considering the effects of atmosphere on beam propagation, it is first necessary to understand how a beam propagates under ideal conditions. Due to the wave nature of light, any light source directed through an aperture will experience divergence. This will cause the radius of the beam, known as the beam waist, to increase in accordance with the divergence angle (Figure 9).

The divergence angle is represented by θ. Note the Gaussian profiles in the margins depicting the decrease in beam irradiance as propagation distance increases.

Figure 9. Beam Waist *w* as a Function of Propagation Distance *z*. Source: [28].

1202 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The beam waist size, divergence angle, and beam wavelength determine the quality of the laser beam. This parameter is known as the beam quality factor and is calculated with the equation:

$$M^2 = \frac{w_0 \pi \theta}{4\lambda} \tag{4}$$

where M^2 is the beam quality factor, w_0 is the beam waist size, θ is the divergence angle, and λ is the beam wavelength [29]. A beam quality factor of 1 indicates an ideal Gaussian irradiance profile. However, current lasers are not perfect and will produce beams with a factor greater than 1. The greater the value of the beam quality factor, the less irradiant the laser beam will be at the target. For this research, a beam quality factor of 3 is used for simulations in order to produce more realistic results.

The size of the laser beam director itself can also significantly impact the qualities of the beam. The effect of beam director diameter on beam waist can be approximated with the equation:

$$w_0 \approx M^2 \left(\frac{2\lambda z}{\pi D} \right) \tag{5}$$

where w_0 is the beam waist size, M^2 is the beam quality factor, λ is the beam wavelength, z is the propagation distance, and D is the beam director diameter [30]. As the beam director diameter increases, the beam waist will decrease and produce a more irradiant beam profile at the target. However, regarding the use of lasers on airborne platforms, it is necessary to keep the beam director as small as possible due to limited space availability and payload capacity. In these simulations, the beam director diameter is set at 25 cm in order to accurately represent a system capable of being mounted to a UAV.

B. EXTINCTION

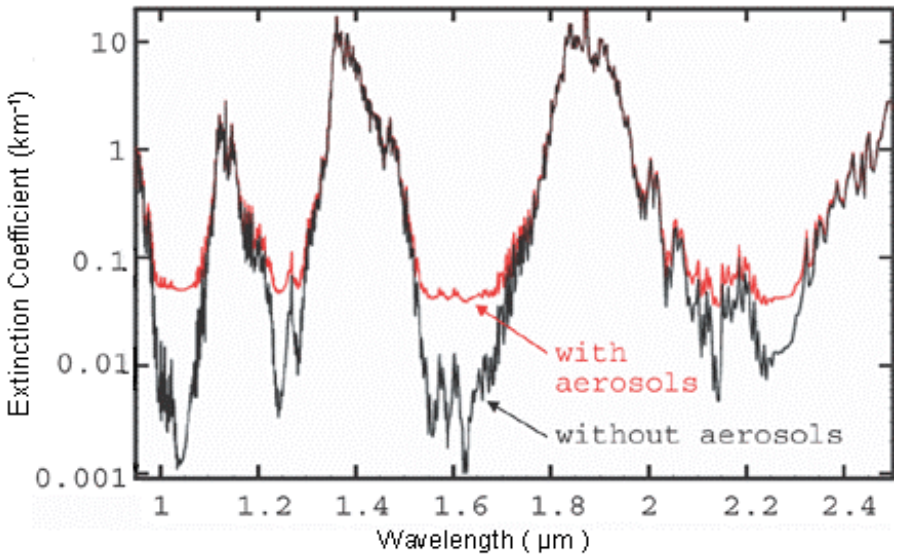
Atmospheric extinction of a laser beam is the result of two separate phenomena. The first of these is absorption, in which atmospheric molecules and aerosol particles absorb incoming photons and thereby decrease the irradiance of the laser beam. Absorption is dependent on the wavelength of the photons and the types of particles present. Since Earth's atmosphere is composed of numerous varieties of molecules and particles, there are only a few narrow wavelength bands that are favorable for beam propagation. Many

1203 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

solid-state lasers currently designed for directed energy applications have wavelengths near 1 μm, which is within a "window" in which light propagates with minimal absorption.

The second effect that causes beam extinction is scattering. Particles in the atmosphere with sizes comparable to the wavelength of light will deflect light rays in random directions. This effect is evident in white clouds, in which water vapor scatters incident light with wavelengths across the visible spectrum. Particles generated as dust or by pollution also scatter light, resulting in a hazy atmosphere (Figure 10).

Figure 10. Haze Created by Atmospheric Scattering of Light by Aerosol Particles. Source: [31].



Laser beam extinction is modeled as an exponential decay. The Beer-Lambert Law provides the mathematical foundation with the function:

$$P(z) = P_0 e^{-\varepsilon z} \tag{6}$$

where *P(z)* is the beam's power as a function of propagation distance, *z* is the propagation distance, P_0 is the initial power, and ε is an extinction coefficient that accounts for wavelength-specific scattering and absorption information and also depends on location, time of day, aerosol concentration, etc. [32]. For the intended application of defeating explosive devices, the extinction coefficient must be as small as feasible, which is largely

1204 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

accomplished by selecting a beam wavelength of approximately 1 μm that tends to minimize extinction (Figure 11).

The red plot includes the presence of aerosols. Note the relatively low extinction coefficient values at approximately 1 μm and 1.6 μm.

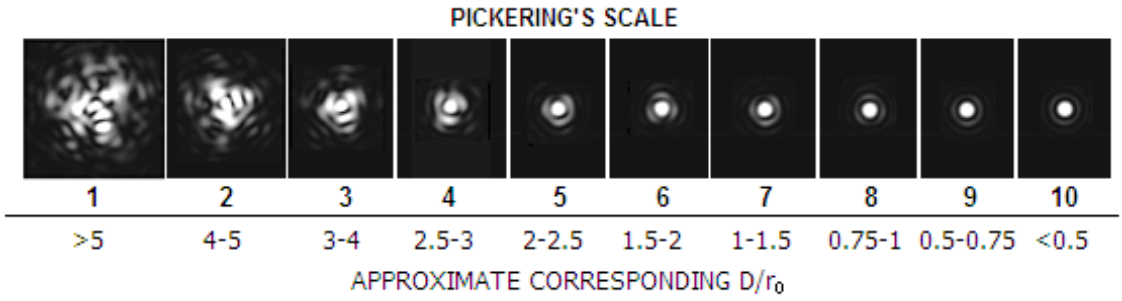
Figure 11. Effect of Wavelength on Beam Extinction. Source: [33].

C. TURBULENCE

As the sun's radiation heats the atmosphere and Earth's surface, it creates differences in air temperature. Accordingly, these cells of air have different densities and pressure that alter their optical indices of refraction. When a light ray transmits between different cells, variations in the indices of refraction cause the light ray to deflect. In addition to this deflection, turbulent cells that are smaller than the laser beam's cross-sectional area will cause portions of the beam to diverge. This divergence results in a loss of coherence, as portions of the beam become out of phase and destructively interfere with each other. The ultimate consequence of turbulence is a distorted, larger, and less intense time-averaged beam spot on the target.

Turbulence is quantified by the refraction structure parameter C_n^2, which is a measure of the change in the air's index of refraction over distance:

1205 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING



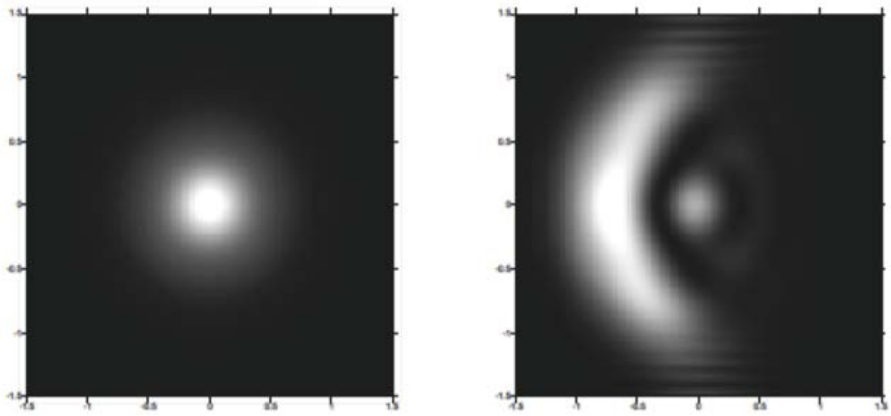
$$C_n^2 = \frac{\overline{[n(x) - n(x+r)]^2}}{r^{2/3}} \quad (7)$$

where *n(x)* is the index of refraction and *n(x+r)* is the index of refraction at range *r* [34]. A value of 10^{-14} $m^{-2/3}$ indicates stronger turbulence, while a value of 10^{-17} $m^{-2/3}$ indicates weaker turbulence.

The refraction structure parameter is of little analytical value by itself, but can be used to estimate the effect of turbulence on beam coherence at the target. The Fried parameter is an estimation of the diameter over which a laser beam maintains transverse coherence throughout a desired propagation distance:

$$r_0 = [0.423(2\pi / \lambda)^2 \int_0^z C_n^2(z)dz]^{-3/5} \quad (8)$$

where r_0 is the Fried parameter, λ is the wavelength, and z is the propagation distance [32]. This formula incorporates C_n^2 along the beam path. As the value of C_n^2 increases, the value of the Fried parameter decreases. For example, given a beam wavelength of 1 μm, a constant C_n^2 value of 10^{-14} $m^{-2/3}$, and a propagation distance of 3 km, the Fried parameter would be approximately 2.4 cm. Under these conditions, any laser beam that is greater than 2.4 cm at its source (established by the beam director diameter) will be significantly affected by turbulence (Figure 12).



Pickering's scale provides a visual approximation of the relationship between the Fried parameter and beam director diameter (denoted as *D*). Each scale number corresponds to a representation of a beam cross-sectional area. As D/r_0 becomes greater than 1, the beam's area will increase and break apart.

Figure 12. Pickering's Scale. Source: [35].

1206 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

D. THERMAL BLOOMING

A laser beam itself can modify the properties of the air it is propagating through. As photons are absorbed by aerosols and molecules along the beam path, energy is released in the form of heat. This heat in turn alters the air's index of refraction by causing the air to expand and become less dense. As the beam continues to propagate through this modified air, it will begin to diverge more quickly than would otherwise be expected via this thermal blooming process [32]. This phenomenon is highly susceptible to temperature-altering effects such as wind. If wind blows across a beam path that is experiencing thermal blooming, it will cool the incident side of the beam and push heated air to the opposite side. The beam will then "bend" into the cooler, and therefore denser, side of the "lens" (Figure 13).

The image on the left depicts a beam profile without wind, while the image on the right depicts beam "bending" caused by a wind blowing from left to right.

Figure 13. Effect of Wind on Thermal Blooming. Source: [36].

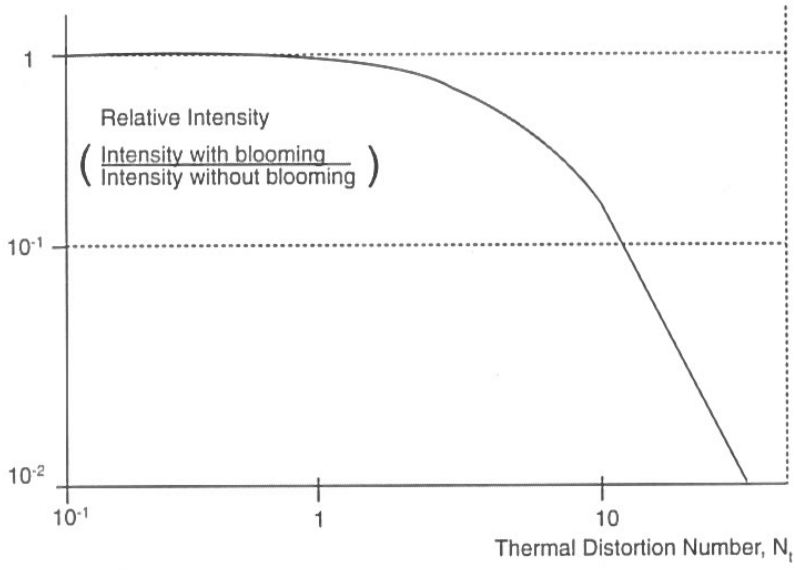
Thermal blooming is roughly characterized through a dimensionless thermal distortion factor, N_t:

$$N_t = \frac{-(dn/dT)}{n\rho c_p} \times \frac{KIz^2}{vr} \tag{9}$$

where n is the air's index of refraction, (dn/dT) is the rate of change in the index of refraction as a result of temperature change, ρ is the air's density, c_p is the heat capacity of

1207 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the air, *K* is the absorption coefficient of the air, *I* is the laser beam's irradiance without thermal blooming, *z* is the distance of propagation, *r* is the beam's radius, and *v* is the crosswind's speed [32]. A larger thermal distortion factor indicates greater beam distortion and decreased intensity at the target. If the crosswind speed or beam radius increase, the thermal distortion number will decrease. However, increasing beam irradiance or propagation distance has the unwanted effect of increasing the thermal distortion number. Figure 14 depicts the effect that the thermal distortion number has on the relative intensity of the laser beam.



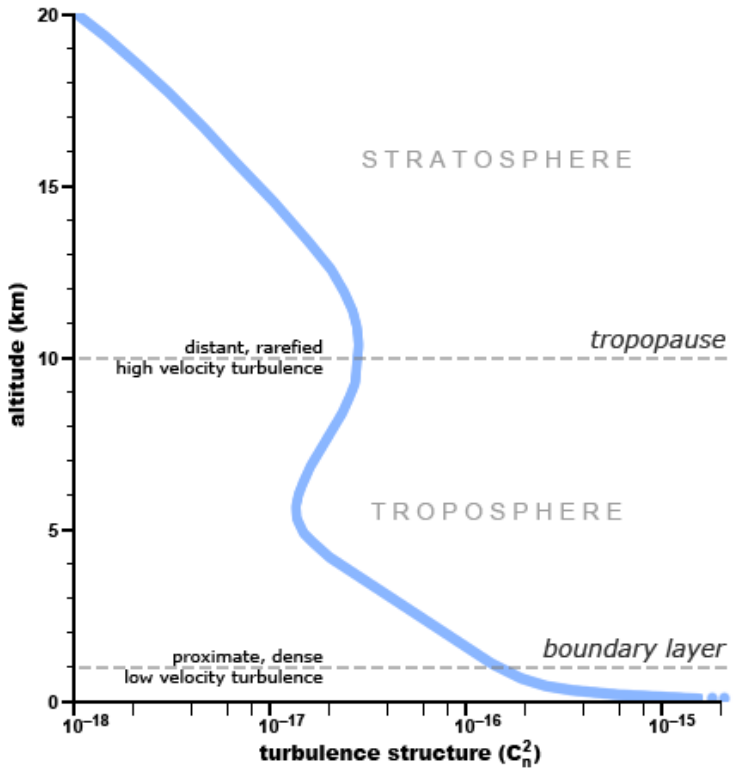


Figure 14. Relationship between Thermal Distortion Number and Relative Intensity. Source: [32].

E. ELEVATION EFFECTS

Using a HEL on an airborne platform to engage ground-based targets has several advantages relative to ground-based lasers. Turbulence is often dramatically reduced at elevation since the platform is further from the ground, and consequently, further from heat sources and surface effects (Figure 15). Although the laser beam is still required to propagate through low-altitude atmosphere as it nears the target, the path over which turbulence is a factor is greatly diminished and restricted to the terminal portion. A ground-

1208 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

based laser beam must suffer the effect over its entire path, including at the beam's origin where it has the greatest effect on the rest of propagation.

Smaller UAVs operate at lower altitude (approximately 2 km) while larger UAVs operate at higher altitude (between 15 km and 18 km).

Figure 15. Effect of Altitude on Atmospheric Turbulence. Source: [37].

Additionally, air density decreases with altitude, which exponentially decreases absorption and increases beam irradiance at the target. The desire to use UAVs as the airborne platform of choice in this research also introduces an advantage regarding thermal blooming. All UAVs currently employed by the U.S. Army are fixed wing aircraft that cannot remain stationary in flight. This means that any laser beam originating from a UAV platform will constantly be moving through unheated air and experience a relative wind proportional to the velocity of the UAV itself. These two factors effectively eliminate thermal blooming as a consideration for the intended application of this research.

1209 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

V. METHODOLOGY

This research simulates air-to-ground laser engagements of ground ordnance using computer-based MATLAB code with user-defined parameters. This chapter will address the variety of parameters used and the reasons for their selection. It will also identify existing simulations used, upon which this research is partially based.

A. TARGET PARAMETERS

Three different types of ground ordnance are modeled in this research: a land mine, IED, and piece of UXO. While it would be impossible to model every explosive device currently in use, the established target profiles emphasize generalized distinctions between the three types. The fundamental differences between these categories are target geometry, outer casing, and explosive material.

1. Geometry

All three types of target have myriad geometries available to choose from. However, the problem can be simplified when approached from the context of this research. Any laser beam intentionally aimed at an object of known range will be deliberately focused in order to reduce its effective area on the target. This focus spot acts as a source term for the heat diffusion equation previously mentioned in Chapter III (Equation 1). The profile of the laser beam is assumed to be a Gaussian distribution modeled by the equation:

$$S = I_{pk}(1-R)e^{-\frac{r^2}{w_{tot}^2}} \tag{10}$$

where S is the source term for the heat diffusion equation, I_{pk} is the peak irradiance of the laser beam, R is the reflectivity coefficient of the target's surface, r is the radial coordinate of the profile, and w_{tot} is the beam waist size. For these simulations, the reflectivity coefficient is assumed to have a value of 0.1, since most explosive devices are intentionally coated in dark non-reflective materials that conceal them within surroundings.

1210 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Ideally, the beam waist is minimized at the target due to focusing (although this can be affected by atmospheric conditions). As a characteristic example, the circular face of the TM-83 AV land mine has a radius of 12.5 cm, with a surface area of approximately 490 cm^2 [22]. Assuming that a typical laser beam has a waist of 3 cm at the target and a cross-sectional area of approximately 28 cm^2, it is reasonable to neglect the effect of geometry on the target's heating since the beam area constitutes less than 6% of the total irradiated surface. Therefore, a standard geometry is used for all three target types during simulations, which consists of a right circular cylinder of 10 cm radius and 10 cm height, with one circular surface being irradiated by the laser beam at its center.

2. Outer Casing

There is a wide variety of casing materials used in explosive devices, which principally reduces to the distinction of plastic versus metal. As previously discussed, metal casings provide for safer handling of the device and have the added effect of increasing shrapnel upon detonation. Steel is a commonly used metal for this purpose and is the material used in many military-grade munitions. Due to this fact, it is appropriate to select steel as the outer casing for the land mine and UXO target profiles, since both are characteristically employed by military forces. Since the thickness of these casings is highly variable between specific devices, a generalized thickness of 5 mm is used for the land mine profile, while a thickness of 2.5 mm is used for the UXO profile. As the casing material is the same in both of these profiles, the simulation results illustrate the effect that casing thickness has on the required dwell times.

Plastic casings are more difficult to detect on the battlefield and are readily available to amateur explosives manufacturers, such as the insurgents and terrorists that employ IEDs. Although IEDs can and have been encased with metal, high density polyethylene is used in this research as the outer casing for the IED profile in order to demonstrate the effect that casing material has on required dwell times. A generalized thickness of 5 mm is used for the IED profile in order to make it comparable to the steel-encased land mine profile, also of 5 mm thickness. Table 1 includes a comprehensive listing of the all outer casing thermal property values used during actual simulations.

Steel (Plain)	7854	60.5	434
Polyethylene (High Density)	959	0.43	2000

3. Explosive Material

Since World War II, RDX is one of the most commonly used components in military-grade high explosives. It is a majority ingredient found in several Composition A, B, and C mixtures widely used by U.S. armed forces (up to 98.5% in Composition A-3, 60% in Composition B-3, and 95% in Composition C-3) [20]. Its thermochemical properties are widely studied and publicized, making it a reasonable assumption that most professional and amateur military forces employ it or its derivatives to some extent. This fact makes it an ideal material to include in generalized models of all three target types, and the thermal property values needed to do so are included in Table 2. These parameters are discussed in the context of the heat diffusion equation in Chapter III (Equation 3).

1800	0.29	2093	2.09	199	$10^{18.5}$

B. ATMOSPHERIC PARAMETERS

In order to establish the atmospheric conditions under which to conduct simulations, it is necessary to consider climate type and weather. Since the combination of these two factors result in a countless number of geographic locations to model, it is necessary to also consider the likelihood that a particular region could become the home of

1212 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

an armed conflict within the near future. Seoul, South Korea and Kandahar, Afghanistan provide highly contrasting climatic conditions with potential for continuing and future military operations. Seoul possesses a temperate climate [40], which is well distinguished from the arid desert climate of Kandahar [41]. The contrast provided by these locations demonstrates the effect that climate has on the required target dwell times.

With climates established, it is also necessary to specify the exact weather conditions under which the simulations will be performed. In order to exemplify the extremes under which engagements could occur, clear and precipitous weather conditions are modeled. Clear weather enables ideal laser beam propagation, while the presence of large water droplets models the most non-ideal condition under which to engage ground ordnance with a laser. As an intermediary, hazy weather conditions are modeled in order to demonstrate the effect of aerosols on the engagements. All regional atmospheric properties are acquired from the Laser Environmental Effects Definition and Reference (LEEDR) database created at the Air Force Institute of Technology.

C. LASER AND PLATFORM PARAMETERS

Bearing the combined effect of target and atmospheric parameters in mind, the laser and platform configuration is critical in achieving a successful simulated engagement. The four most important parameters in this regard are the laser beam quality, laser beam wavelength, platform altitude, and laser power output.

1. Laser Beam Quality and Wavelength

As previously discussed, laser beam quality has a significant impact on the beam's irradiance at the target. A beam quality factor of 3 is used in these simulations to model a realistic laser. Atmospheric absorption of laser energy is highly dependent on the laser's frequency. In order to minimize absorption, a lasing wavelength of 1.0642 μm is used in these simulations. While other wavelength "windows" exist that minimize absorption, 1 μm is a commonly used wavelength in a multitude of existing solid-state systems.

1213 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

2. Platform Altitude

The capabilities of the UAV platform are the driving factor in determining the altitude at which the laser will engage the target. Generally, the greater the size and power of a UAV, the greater its maximum operating altitude, or service ceiling, will be. The RQ-7B Shadow, which is the smallest UAV currently used that could potentially carry a laser system, typically operates at an altitude of 2.4 km to 3 km during the day [42]. Conversely, the RQ-4 Global Hawk, which is likely the largest current UAV that could be used in this capacity, has a service ceiling of over 18 km [43].

Since increasing altitude also increases the amount of atmosphere through which the laser beam must propagate, a minimal altitude is ideal for these simulations. Three different altitudes of 1 km, 4 km, and 7 km are considered in this research to provide a reasonable range of values that could accommodate any tactical concerns. While 7 km is certainly not a limit imposed by existing UAV platform capabilities, it is within the upper limit of altitudes that enable engagement dwell times to remain minimal, which is kept within 60 seconds in this research.

3. Laser Power Output

In order to use an airborne platform for these engagements, the laser system must be kept as compact as possible with regard to SWaP design considerations. This is especially significant when the proposed airborne platform is a UAV, which are typically far smaller and less powerful than their manned counterparts or ground-based platforms. Considering the material properties of the proposed targets and the propagation distances of the laser beam, a power output less than 2.5 kW would likely be insufficient to achieve the desired effect, especially at higher altitude and in non-ideal weather conditions.

Fiber lasers are currently a viable solid-state laser option for producing outputs in the kilowatt range while maintaining beam quality and minimizing weight. For example, IPG Photonics, which specializes in producing industrial cutting lasers, manufactures a 1 μm continuous wave ytterbium fiber system with a scalable power output of 1 kW to 10 kW that weighs less than 380 pounds [44]. Such a system would be ideal for providing the necessary power output while minimizing size and weight. Accordingly, this research

1214 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

considers the effects of a 2.5 kW, 5 kW, and 10 kW power output in order to explore a range of powers likely to be mounted onboard a UAV platform.

D. SIMULATION TOOLS

This research relies on a pair of simulation tools developed at renowned defense research institutions. This section will briefly expound on both the inputs and outputs required to incorporate these tools into the simulated engagements.

1. LEEDR

As mentioned, LEEDR is a database of atmospheric conditions that generates regional approximations for the light propagation coefficients discussed in Chapter IV. LEEDR enables the user to control the weather conditions at specified locations using preset values or averages unique to that particular location. For these simulations, regional weather monitoring stations known as "ExPERT" sites in LEEDR will be used. Incheon International Airport is the ExPERT site representative of Seoul, while Kandahar Air Base is the ExPERT site used for the city of Kandahar. With one exception, all weather profiles used are representative of summer weather conditions (July), with the ambient temperature taken as the daily average for that location. The one exception is the precipitous weather profile for Kandahar since southern Afghanistan typically only receives rain during the winter months, which LEEDR bases on average conditions in the month of January. Clear and hazy profiles utilize a relative humidity percentile setting of 50% (i.e., more humid than 50% of measured days, and so represents a typical humidity for that location in January or July). Precipitous profiles utilize a relative humidity percentile setting of 99%. The widely known Hufnagel-Valley model for turbulence [45] was applied to all profiles as well.

Clear weather profiles utilize a Global Aerosol Data Set (GADS) multiplier of 1, which simulates a typical aerosol concentration for that location. The clear weather profiles do not include any cloud or rain effects. Precipitous weather profiles utilize a GADS multiplier of 0.2, the addition of "moderate rain" (a LEEDR setting that corresponds to 12.5 mm per hour), and a cloud layer at 10 km altitude. While a cloud layer at this height is unrealistic, it enables the simulation to demonstrate the effect of rain throughout the path

1215 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

of propagation. Otherwise the extinction effect generated by a cloud layer would completely disrupt a laser beam and prevent target autoignition (this effectively makes any simulations performed at 4 km and 7 km platform altitude under precipitous conditions unrealistic and therefore irrelevant). Finally, hazy weather profiles utilize a GADS multiplier of 3, which simulates high aerosol concentration, and do not include any cloud or rain effects. See Table 3 and Table 4 for a complete listing of settings used to generate the LEEDR weather profiles.

Table 3. Seoul Weather Profile Settings.

Weather	Aerosol Model	Aerosol Multiplier	Rain	Season	Temp.	Relative Humidity Percentile
Clear	GADS	1	-	Summer	Daily Avg.	50%
Precipitation	GADS	0.2	12.5 mm per hour	Summer	Daily Avg.	99%
Haze	GADS	3	-	Summer	Daily Avg.	50%

Precipitation	GADS	0.2	12.5 mm per hour	Winter	Daily Avg.	99%
Haze	GADS	3	-	Summer	Daily Avg.	50%

1216 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

2. ANCHOR

Developed at the Naval Postgraduate School, ANCHOR is a scaling code that simulates the effect of atmospheric propagation on a laser beam. Its inputs include the LEEDR weather profile, laser parameters, and platform conditions. Its outputs include the beam waist size and beam irradiance over an array of cross ranges defined by the user. ANCHOR is capable of modeling the effects of extinction, turbulence, and thermal blooming, although the thermal blooming capability is not used in these simulations for the reasons discussed in Chapter IV. For this research, ANCHOR is used as a preliminary simulation for each test case that provides the laser beam parameters at the target prior to and during heat diffusion.

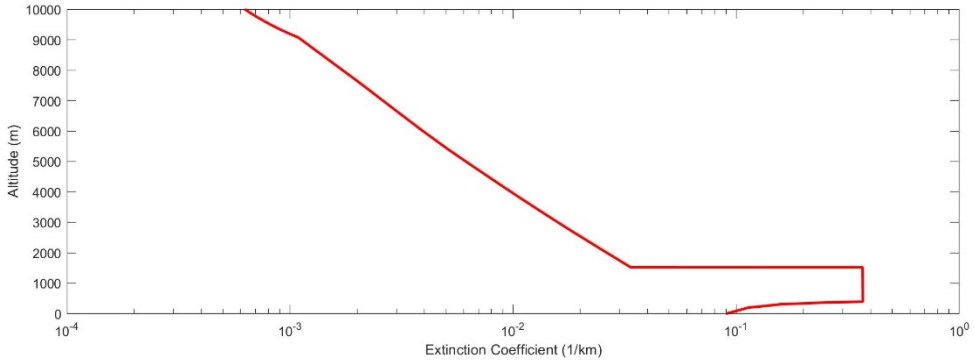
1217 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

VI. RESULTS AND CONCLUSIONS

This chapter discusses the effect that each independent variable has on required dwell times based on results obtained through simulation. The chapter concludes by determining the capabilities of laser systems with different output powers and the potential for mounting them onboard different UAVs based on SWaP requirements.

A. EXTINCTION PROFILES

Climate and weather conditions dramatically alter the atmospheric effects on laser beam propagation. Specifically, the effects of beam extinction are increased from clear to hazy weather, and even further increased when accounting for the presence of precipitation. See Figure 16, Figure 17, and Figure 18 for LEEDR-generated data regarding the extinction coefficient of various weather types in Seoul, South Korea. For reference, see Table 3 and Table 4 for the settings used to generate these figures.



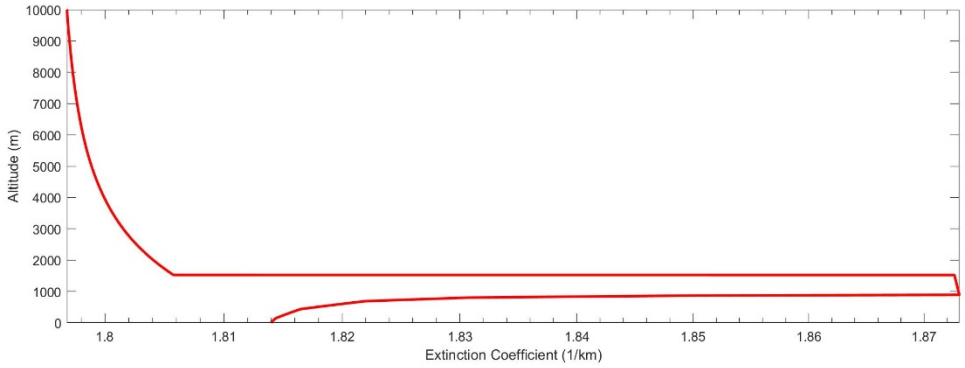


Figure 16. Extinction Coefficient for Clear Seoul Weather Conditions.

1218 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Note the scale used for the extinction coefficient in this figure is linear (unlike the logarithmic scales used Figure 16 and Figure 18).

Figure 17. Extinction Coefficient for Precipitous Seoul Weather Conditions.

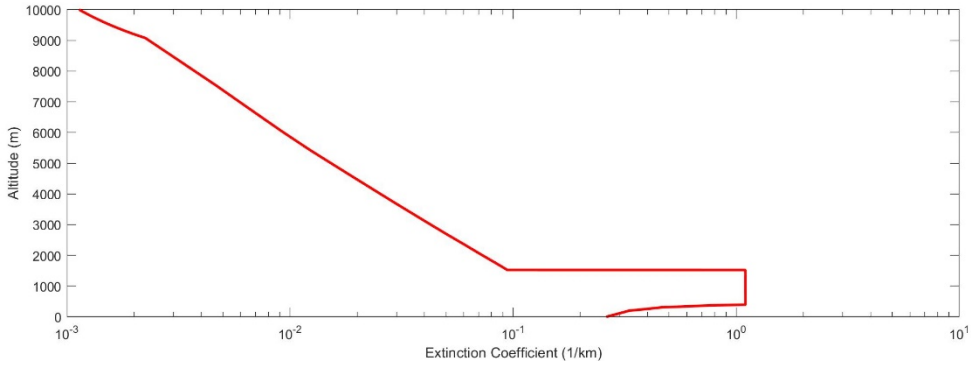

Figure 18. Extinction Coefficient for Hazy Seoul Weather Conditions.

The plots for extinction coefficient share the same general characteristics across both climates and all three weather profiles. From ground-level to an altitude of approximately 1 km (the atmospheric boundary layer), the coefficient value increases. However, just above the boundary layer at approximately 2 km altitude, the coefficient value decreases dramatically and then steadily declines even further with increased altitude. An increase in extinction coefficient value corresponds with a decrease in the amount of laser output power that actually reaches the target in accordance with the Beer-Lambert Law (Equation 6). Of note, the extinction coefficient data for Kandahar, Afghanistan indicates that, for similar weather types, the coefficient value generally remains less than that in Seoul across the platform altitudes simulated. The difference in

1219 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

extinction coefficient profiles can be explained by the relative abundance of atmospheric moisture near Seoul and the absence thereof near Kandahar. The extinction coefficient is inversely related to the surface visibility generated by LEEDR for each profile. Table 5 displays the effects that climate and weather type have on surface visibility.

Table 5. Effects of Climate and Weather on Surface Visibility.

	Seoul, South Korea			Kandahar, Afghanistan		
	Clear	Precipitation	Haze	Clear	Precipitation	Haze
Surface Visibility (km)	23.7	1.64	8.50	33.3	1.64	12.0

The key conclusion to draw with regard to climate type is that, based on the data for these two locations, drier climates will produce more favorable atmospheric conditions for laser beam propagation (not considering the effects of sand storms). This effect is manifested in universally reduced dwell times for targets engaged in an arid desert environment, even when other independent variables are adjusted. In later sections, the Seoul climate profiles will be used to identify the extreme limits under which target autoignition can occur.

B. EFFECT OF WEATHER

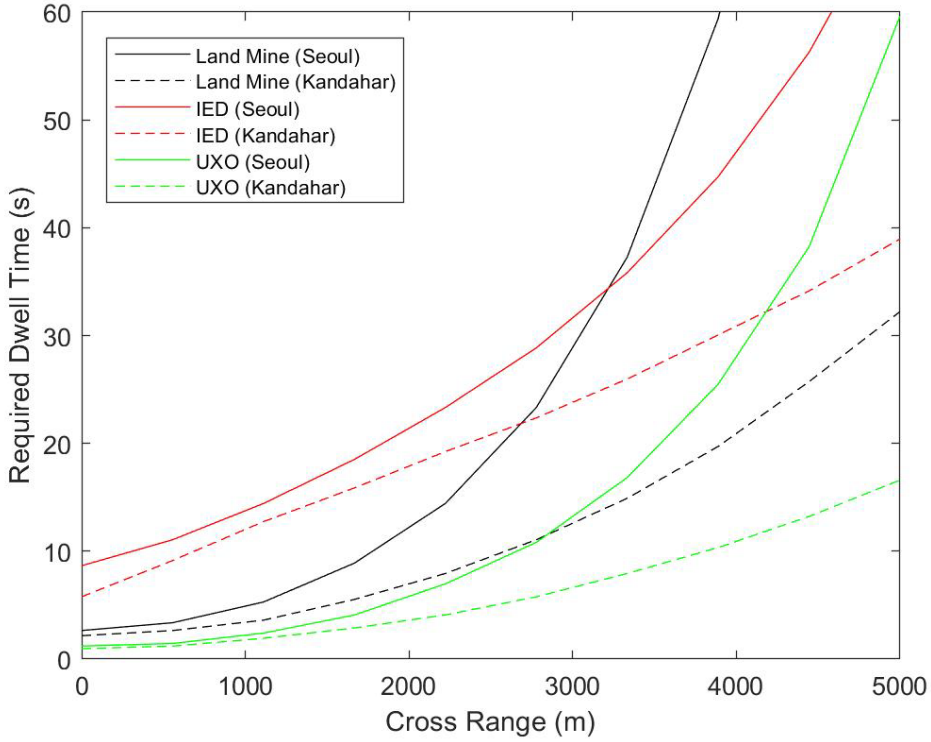
To illustrate the effect of weather type on required dwell time, platform altitude, output power, and target type are kept constant. The comparison in Figure 19 displays data taken from 1 km platform altitude, 2.5 kW output power, and land mine target engagements.

1220 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Note that the plot for hazy Seoul weather conditions stops at a cross range of approximately 1.75 km. This is due to the fact that the simulation is unable to achieve autoignition in the target within 60 seconds of dwell time at greater cross ranges.

Figure 19. Simulation Results for 1 km Platform Altitude, 2.5 kW Output Power, Land Mine Target Engagements.

Predictably, clear weather conditions produce the most favorable dwell times. The reduced presence of atmospheric particles corresponds with reduced beam extinction. Hazy weather conditions produce the next lowest dwell times, since the high concentration of aerosols results in increased beam scattering and absorption. Finally, precipitous weather produces the highest dwell times since the presence of large water droplets effectively extinguishes the beam at greater cross ranges.



This data supports the conclusion that, although required dwell times are severely degraded, a low-power 2.5 kW laser is still capable of successfully engaging ground ordnance across all three weather types simulated. In precipitous conditions, the cross range is reduced to approximately 500 m for a 2.5 kW laser system. However, in clear

1221 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

conditions, the same system can achieve autoignition conditions in the target at a cross range in excess of 5 km.

C. EFFECT OF TARGET TYPE

To illustrate the effect of target type on required dwell times, engagements in clear weather, at 1 km platform altitude, and with 2.5kW output power are considered. See Figure 20 for simulation results.

The plots for land mine and IED targets engaged under similar climate conditions (Seoul) intersect at a cross range of approximately 3.25 km, which indicates that the land mine is a more difficult target to defeat at greater cross ranges under these simulation parameters.

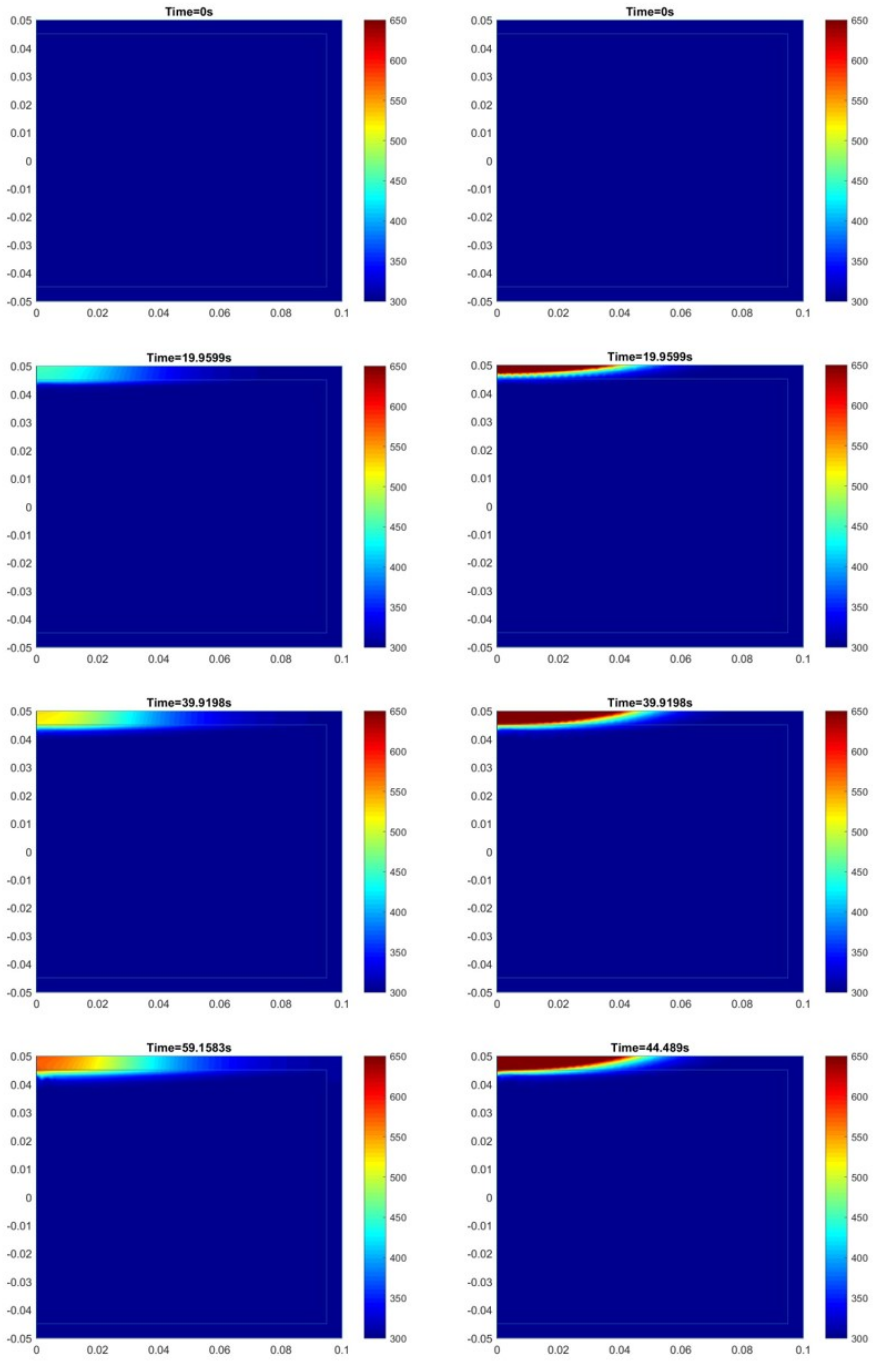


Figure 20. Simulation Results for Clear Weather, 1 km Platform Altitude, 2.5 kW Output Power Engagements.

Outer casing thickness has a significant effect on required dwell time. When comparing the two steel-encased targets, the UXO target profile (2.5 mm of casing) universally produces lower dwell times than the land mine target profile (5 mm of casing).

1222 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Casing material has an even more dramatic effect on dwell times. The dwell times for the IED target profile, with its 5 mm of high density polyethylene casing, increase exponentially with respect to increasing cross range similarly to the steel-encased targets. However, the rate of this exponential increase is noticeably less than that for the steel profiles. Even though the IED target requires greater dwell times at lower cross ranges, the IED target data intersects the land mine target data at a cross range of approximately 3.25 km in Figure 20, after which the IED profile for Seoul actually requires lower dwell times than the land mine profile (also for Seoul). This intersection is indicative of different heating behaviors for both materials as beam irradiance is affected by increases in the propagation path (Figure 21).

1223 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The figures on the left represent heating of a land mine target while the figures on the right represent heating of an IED target. For reference, the axes are in units of meters while the color scale is in units of kelvins. The bottom figure of each target is a depiction of the heating profile immediately prior to autoignition.

Figure 21. Target Cross-sectional Heating in Seoul Climate, Clear Weather, 1 km Platform Altitude, 2.5 kW Output Power, 3.89 km Cross Range Engagements.

1224 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Due to the insulating nature of polyethylene, heat deposited by the laser beam remains relatively local to the beam spot on the surface of the target, where it accumulates and diffuses at a faster rate towards the explosive interface than it does radially outward. However, being a conductive material, steel casing diffuses more heat radially outward from the beam spot. When the beam irradiance is high (i.e., when the spot size is small at shorter cross ranges), the heat diffuses rapidly enough in both directions (towards the explosive interface and radially outward) that the target autoignites. When beam irradiance is low (i.e., when the spot size is larger at longer cross ranges), the radial diffusion prevents enough heat from reaching the explosive interface and autoigniting the RDX in a reasonable amount of time.

Since the melt temperature of high density polyethylene ranges between 383 K and 408 K [46], there is concern that the amount of heat deposited by the laser beam will melt the IED target's outer casing prior to explosive autoignition. However, it is possible to approximate the amount of total energy deposited by the laser beam that would be required to achieve such a state transition. The energy required to melt a material that is being irradiated by a laser beam can be approximated using the equation:

$$E_m \approx H_f \rho \pi w_{tot}^2 l \tag{11}$$

where E_m is the required melt energy, H_f is the heat of fusion (245 kJ/kg for high density polyethylene [46]), w_{tot} is the beam waist size, and l is the material thickness. Conversely, the total energy deposited by the laser beam can be approximated as:

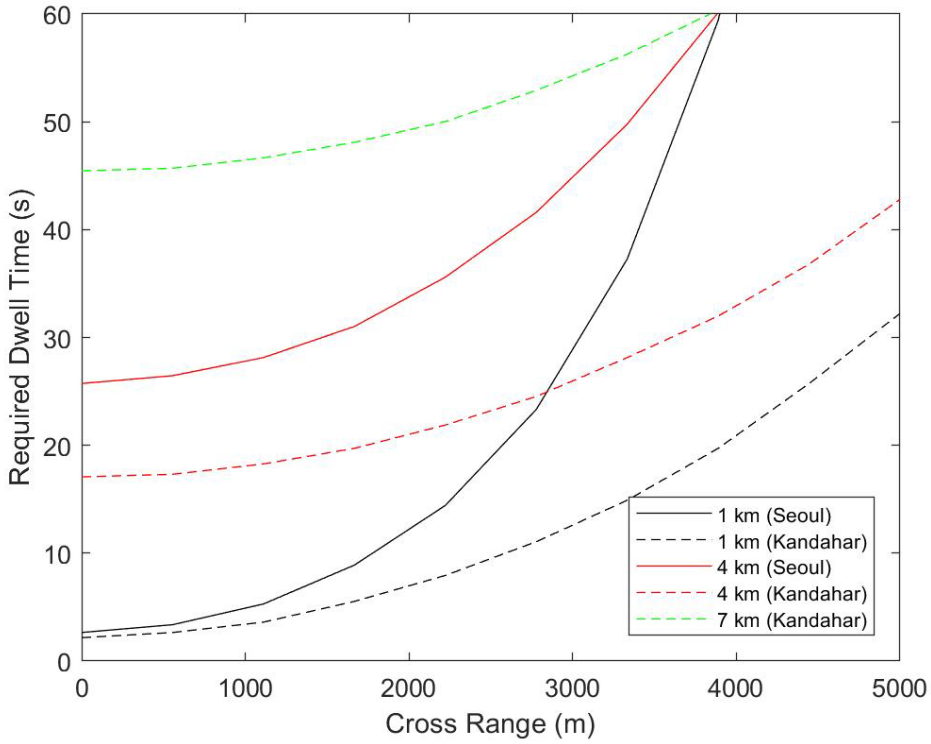
$$E_b \approx I_{pk} \pi w_{tot}^2 t_d (1-R) \tag{12}$$

where E_b is the energy deposited by the beam, I_{pk} is the peak irradiance of the beam, t_d is the required dwell time for autoignition, and R is the reflectivity coefficient of the material. Relating Equation 11 and Equation 12 produces the equation:

$$G \approx \frac{H_f \rho l}{I_{pk} t_d (1-R)} \tag{13}$$

where G is the fraction that relates the energy required to melt the casing material to the total energy deposited by the laser beam. Upon conducting this calculation for a sample of simulations, the percentage is approximated to remain below 10% of the total energy deposited by the laser beam. It is therefore a reasonable assumption to neglect the energy

1225 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING



consumed by melting with regard to the time scales and polyethylene casing thickness modeled in these simulations.

In addition to melting, there is concern over the effect imposed by the removal of polyethylene casing while the target is irradiated (either by burning or gravity). In either case, the removal of mass would reduce the time required for the heat front to diffuse in accordance with the heat diffusion equation mentioned in Chapter III (Equation 1). In the case of burning (high density polyethylene itself has an autoignition temperature of approximately 613 K [46]), the energy released by burning the casing would actually contribute to the heat front diffusion. The ultimate effect of casing removal in either situation would be a reduction in the dwell time required to achieve autoignition in the target. Therefore, by not considering the effect of casing removal in this research, the simulation results are likely to be conservative (i.e., higher dwell times) than those that would be achieved through experimentation. Having established that the land mine and IED target types are the most difficult with which to achieve autoignition conditions, they are used as the standards by which to establish the requirements of a laser system intended to defeat ground ordnance.

D. EFFECT OF PLATFORM ALTITUDE

Simulated engagements performed in clear weather, with 2.5 kW output power, and against land mine targets are used to compare the effect of platform altitude on required dwell time (Figure 22).

1226 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The plot for an engagement in Seoul at 7 km platform altitude is not available since the simulated laser beam is unable to achieve autoignition conditions in the target within 60 seconds of dwell time.

Figure 22. Simulation Results for Clear Weather, 2.5 kW Output Power, Land Mine Target Engagements.

There is a universally strong relationship between platform altitude and the required dwell time to achieve autoignition conditions. This can be explained by the increased effects of scattering, absorption, and turbulence as the propagation path of the laser beam increases. Although lower altitudes result in reduced engagement dwell times, they are also disadvantageous for UAV operations. An aircraft operating at low altitude is more vulnerable to anti-aircraft defenses, and relatively slow-moving UAVs are particularly vulnerable. Since low-level cloud layers typically exist below 2 km altitude [47], the only tactical reason for a UAV to operate below this altitude would be the presence of rain clouds (hence why precipitous weather simulations are relevant at 1 km altitude, but not 4 km or 7 km) or in overcast conditions. However, conducting engagements at high altitude places a tax on the laser system's requirements. Of note, the plots for the 1 km platform altitude and 4 km platform altitude engagements in Seoul converge at a cross range of

1227 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

approximately 4 km. This can be attributed to the effect of increased extinction coefficient in the atmospheric boundary layer. While the simulation performed at 1 km platform altitude must propagate almost the entire distance with a very large coefficient value, the simulation performed at 4 km platform altitude only propagates through the boundary layer for approximately half of the distance to the target.

E. EFFECT OF OUTPUT POWER

Engagements performed in clear weather, at 1 km platform altitude, and against land mine targets are used to determine the effect of laser output power on required dwell times. See Figure 23 for a visual comparison of the data.

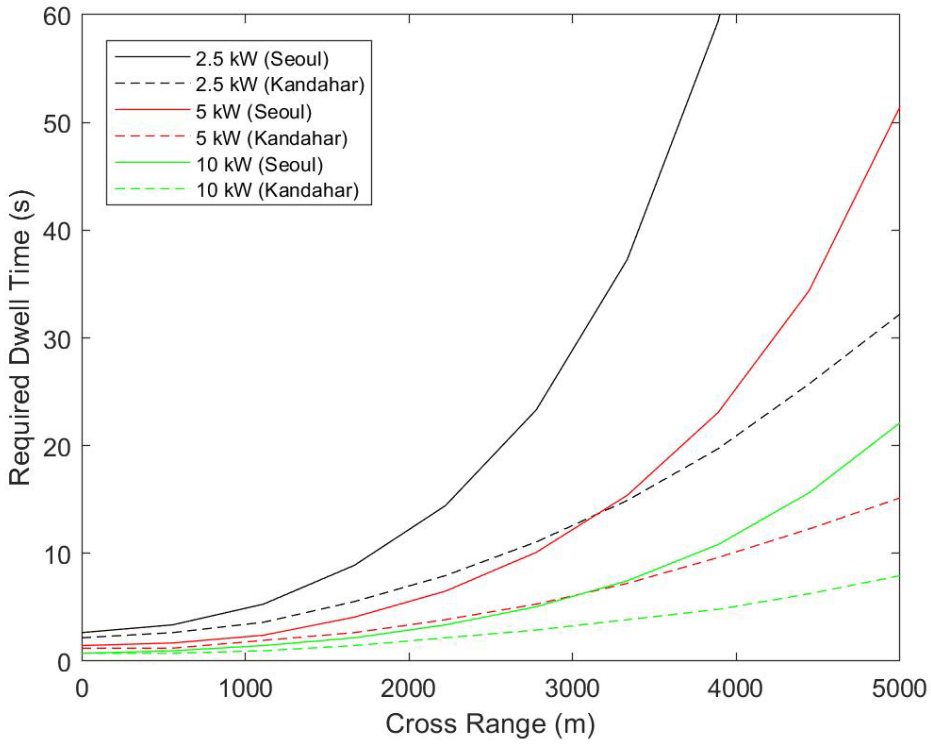


Figure 23. Simulation Results for Clear Weather, 1 km Platform Altitude, Land Mine Target Engagements.

As expected, laser output power plays a significant role in determining the required dwell time. Greater output power means that more energy is deposited at the surface of the

1228 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

target and consequentially increases the diffusion speed of the heat front through the outer casing. Of all the independent variables tested in this research, laser output power is the most significant with regard to designing a system capable of achieving target autoignition across all conditions.

As identified in previous sections of this chapter, engagements that occur in a temperate climate (Seoul) are non-ideal relative to those that occur in a drier climate (Kandahar). Additionally, depending on the platform altitude, precipitous and hazy weather are the most disruptive weather conditions regarding laser beam propagation. Finally, land mine and IED target types are the most difficult to defeat. These conclusions enable identification of the maximum capabilities of the three simulated output powers. A temperate climate with precipitous weather at 1 km platform altitude is the most non-ideal situation under which a 2.5 kW output power can achieve autoignition in the two most difficult target types (Figure 24).

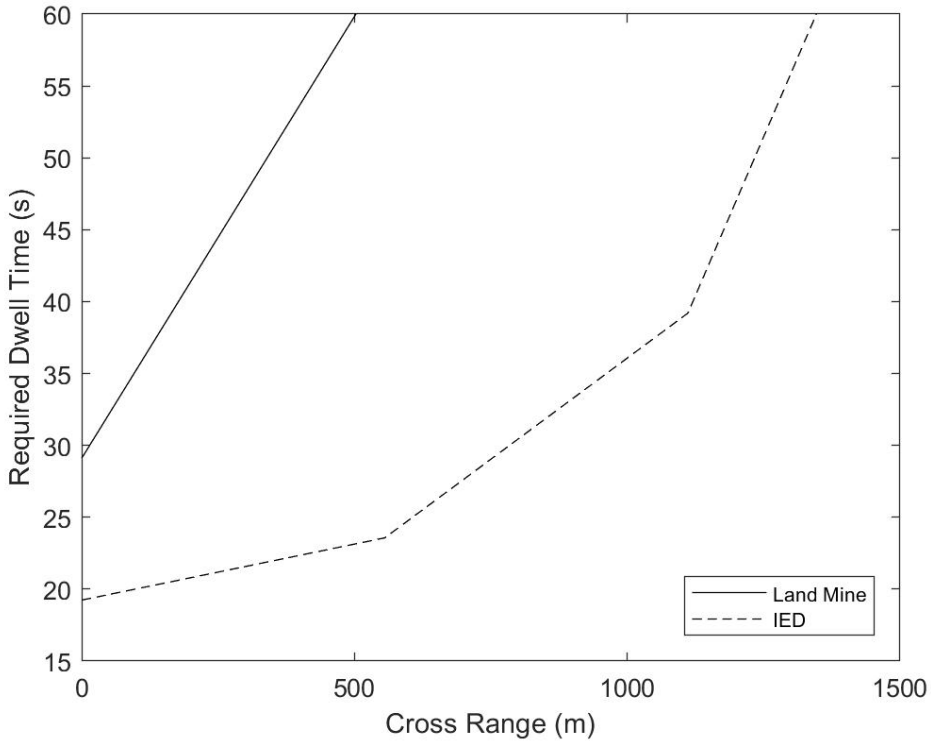

Figure 24. Simulation Results for a Seoul Climate, Precipitous Weather, 1 km Platform Altitude, 2.5 kW Output Power Engagement.

1229 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Increasing the output power of the laser to 5 kW enables target autoignition at a platform altitude of 4 km in hazy weather conditions (Figure 25).

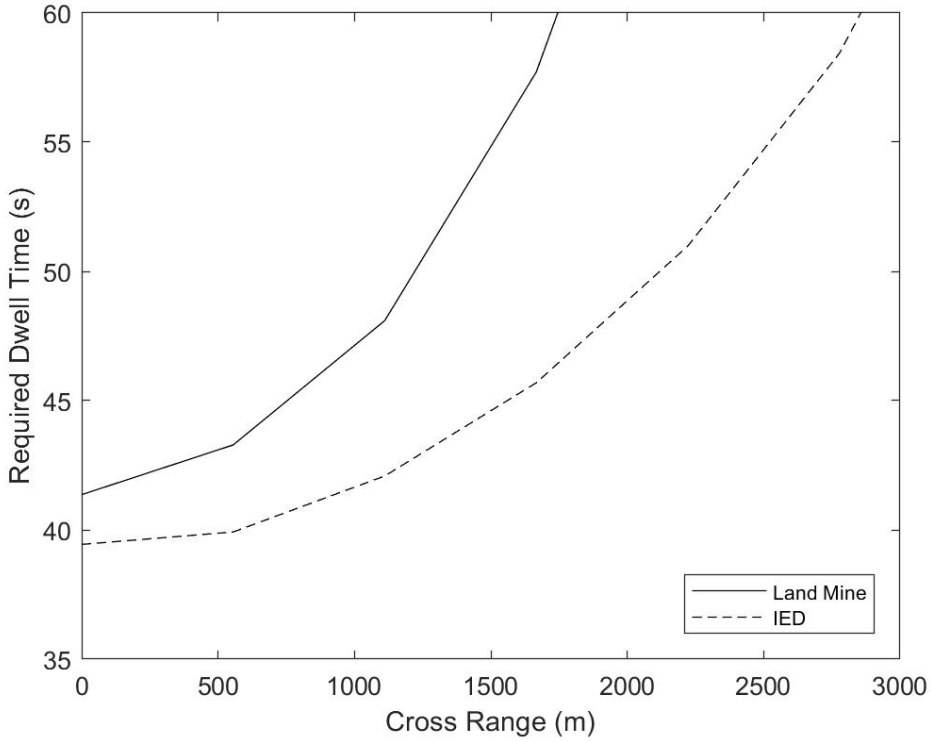

Figure 25. Simulation Results for a Seoul Climate, Hazy Weather, 4 km Platform Altitude, 5 kW Output Power Engagement.

1230 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Finally, the maximum simulated output power of 10 kW enables target defeat at a platform altitude of 7 km in hazy weather conditions (Figure 26).

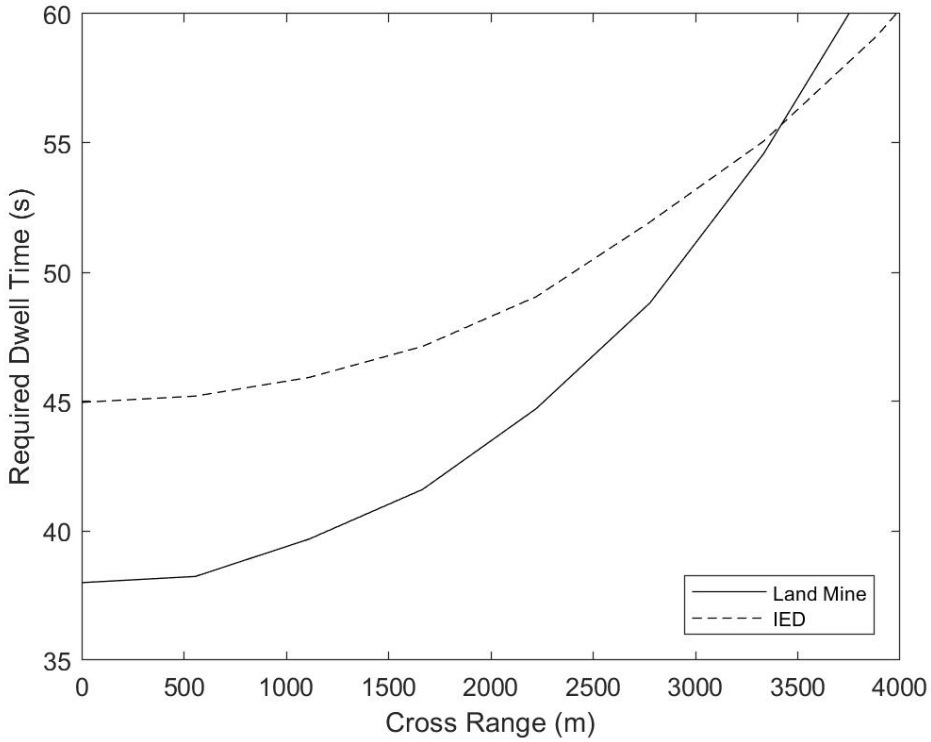

Figure 26. Simulation Results for a Seoul Climate, Hazy Weather, 7 km Platform Altitude, 10 kW Output Power Engagement.

F. CONCLUSIONS

It is feasible to engage and defeat ground ordnance using an airborne solid-state laser. At a platform altitude of 1 km, these simulations indicate that all three tested output powers are capable of achieving autoignition conditions in both climates, across all weather profiles, and against each target type. The most restrictive variable is weather, which effectively limits the platform altitude to the cloud layer during precipitous weather. Additionally, in order to defeat all three target types in clear or hazy weather and in either climate, the minimum required output power increases to 5 kW for 4 km platform altitude engagements and 10 kW for 7 km platform altitude engagements.

1231 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The concept of using UAV-mounted solid-state lasers to defeat ground ordnance bears utility. As an example, the IPG Photonics YLS-3000-SM system produces a similar beam to the one simulated in this research with an output power of 10 kW and contained in a compact 0.95 m^3 package [48]. A similar model listed by the company weighs less than 380 pounds and has a published wall-plug efficiency greater than 50% [44]. This means that the system could be operated with a power source that outputs an average of 20 kW. While these SWaP requirements are too large for smaller UAVs such as the RQ-7B Shadow, they do not supersede the capabilities of mid-size UAVs such as the MQ-1C Gray Eagle, which has a payload capacity of 1,075 pounds [49]. This would enable current U.S. Army forces to maintain a responsive airborne ordnance-clearing asset at the division echelon.

There are many opportunities for expansion of this research. The diffusion of heat to achieve autoignition is just one defeat mechanism particular to a specific target type. Different target types with other defeat mechanisms should be studied in order to grasp the full utility of airborne laser systems. Additionally, expanding the selection of platforms beyond UAVs could create possibilities with regard to increased SWaP availability. Rotary and fixed-wing aircraft could theoretically carry laser systems with greater output power, which in turn increases the feasibility of defeating different target types. As solid-state laser systems continue to become more compact and powerful, it is highly likely that airborne laser weapons will become a fixture on future battlefields.

14. ABSTRACT
The US Army is experiencing a cultural shift away from years of low intensity, counter-insurgency operations toward large scale combat operations with a near-peer or peer threat. The shift includes a major change from brigade-centric operations to divisions and corps serving as the primary warfighting headquarters. Headquarters must now not only provide resources, but simultaneously direct the conflict in multiple domains, including space and cyber-space. US Army Aviation can be a significant force multiplier, but only when used effectively. Army Aviation continues to gain ground through lessons learned from the readiness training centers on how best to reach deep in multi-domain operations. Army Aviation faces many obstacles to continue to be a force multiplier. The 2015 *Field Manual 3-04, Army Aviation*, set new expectations for large scale combat operations, but improvements in training, equipment, and doctrine are necessary to achieve what *FM 3-04* demands conceptually. The complex battlefield set by near-peer and peer threats restricts Army Aviation's freedom of maneuver with anti-access and area-denial systems. To respond to such threats, Army Aviation currently fields upgrades to its legacy fleet of helicopters, but this approach consumes resources that could go towards the future vertical lift fleet. For Army Aviation to be ready to fight today, they must continue to improve the legacy fleet. However, the more Army Aviation spends on updating the legacy fleet, the less it is investing in the future airframes. Additionally, the current fleet has limited potential for further modifications. The key question is whether such modifications to the legacy fleet will be enough to combat the challenges faced in the complex and lethal battlefield of large scale combat operations against a near-peer or peer threat. This monograph addresses those questions surrounding the shift from counter-insurgency to large scale combat operations for Army Aviation.

Abstract

Future Roles of Army Aviation in Large Scale Combat Operations, by MAJ Kenneth R. Dougher II, US Army, 47 pages.

The US Army is experiencing a cultural shift away from years of low intensity, counter-insurgency operations toward large scale combat operations with a near-peer or peer threat. The shift includes a major change from brigade-centric operations to divisions and corps serving as the primary warfighting headquarters. Headquarters must now not only provide resources, but simultaneously direct the conflict in multiple domains, including space and cyber-space. US Army Aviation can be a significant force multiplier, but only when used effectively. Army Aviation continues to gain ground through lessons learned from the readiness training centers on how best to reach deep in multi-domain operations. Army Aviation faces many obstacles to continue to be a force multiplier. The 2015 *Field Manual 3-04, Army Aviation*, set new expectations for large scale combat operations, but improvements in training, equipment, and doctrine are necessary to achieve what *FM 3-04* demands conceptually. The complex battlefield set by near-peer and peer threats restricts Army Aviation's freedom of maneuver with anti-access and area-denial systems. To respond to such threats, Army Aviation currently fields upgrades to its legacy fleet of helicopters, but this approach consumes resources that could go towards the future vertical lift fleet. For Army Aviation to be ready to fight today, they must continue to improve the legacy fleet. However, the more Army Aviation spends on updating the legacy fleet, the less it is investing in the future airframes. Additionally, the current fleet has limited potential for further modifications. The key question is whether such modifications to the legacy fleet will be enough to combat the challenges faced in the complex and lethal battlefield of large scale combat operations against a near-peer or peer threat. This monograph addresses those questions surrounding the shift from counter-insurgency to large scale combat operations for Army Aviation.

1249 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Acknowledgments

I would like to thank my monograph director, Mark T. Calhoun, Ph.D., and my seminar leader, Colonel Geoffrey A. Whittenberg for their patience and consistent support throughout this research and analysis project. Thank you to my seminar classmates that really made SAMS such a great experience. A special thank you to MAJ Philip Neri for suffering through countless drafts of this piece, MAJ David Jones for providing invaluable feedback, and a thank you to my editor, Ms. Venita Krueger. Last, but not least, I am blessed and grateful to have the love, support, and patience of my family and friends, especially my better half, Tina, and our two amazing children, Kenneth, and Caitlin.

1253 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Introduction

> Large-scale ground combat is more likely today than at any point since the end of the Cold War. And the risk of great power conflict will likely persist into the distant future. While the last 17 years of limited contingency and counterinsurgency operations were necessarily brigade-centric, conflict with a peer and near-peer threats requires a continued culture shift as well as the optimization of EABs (echelons above brigade) into highly capable divisions, corps, field armies, and theater armies.
>
> — Lieutenant General Michael D. Lundy, Commanding General, US Army Combined Arms Center

Background

Since the American Civil War, Army Aviation has played a role in US warfare. Army Aviation has continually adapted and strived to provide the ground force commander additional options, from deep attacks to reconnaissance, air assaults, medical evacuations, and more. In the most recent war on terrorism, Army Aviation provided these capabilities to the ground force commander which enabled numerous options, saving thousands of lives. While Army Aviation has proven itself as a combat multiplier in the current fight, past results may not be indicative of future success.

Former combat aviation brigade (CAB) commander Colonel Jimmy Blackmon observed that "pilots are the products of their experiences." Currently, there is a pressing challenge to create realistic training opportunities to prepare leadership for the rising threat of conflict with a peer or near-peer adversary. Army Aviation's primary focus over the past decade focused on meeting the requirement for training and completing missions during specific rotational deployments to stable theaters, with a focus on environmental conditions. In the Gulf War, close air support was not the primary goal for the air component. However, in the mountains of the Regional Command East, Afghanistan, it was essential to the mission. The primary objective for the limited contingency was close air support, but as the US Army gravitates back to the pressing challenge of Large Scale Combat Operations (LSCO), Army Aviation must be prepared to increase their deep attack and interdiction capabilities. LSCO, unlike counter-insurgency (COIN),

1254 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

will challenge the Army in all domains. In recent history, the Army has assumed air superiority and not contended with electronic warfare, but, within LSCO, these challenges will present themselves.[1]

The concept of AirLand Battle has evolved since its inception in US Army doctrine in the 1970s, and first significant test in the Gulf War. As defined in the 1986 *Field Manual (FM) 100-5, Operations*, AirLand Battle involves "securing or retaining the initiative to accomplish the mission by throwing the enemy off balance with a powerful blow from an unexpected direction and following up rapidly and continuously to achieve the higher commander's goals." The two main Army Aviation elements of AirLand Battle: close air support and deep attack, have not changed significantly since the Gulf War, but evolution in technology changed the manner in which aviation executes these roles. Improved technology has brought in different weapon systems for attack helicopters (AH), surveillance, reconnaissance, and interdiction technology for unmanned aerial systems (UAS), utility helicopter (UH) 60M and cargo helicopter (CH) 47F models with digital readouts, and hovering features for lift helicopters to assist with air assault operations.[2]

Despite advances in technology, aviation brigades still face numerous challenges. According to two battalion commanders of the 101st Airborne Division, deployed aviation commanders had similar numbers of attack helicopters (AH 64s) and observation helicopters (OH 58Ds), but did not have enough CH-47Fs, the US Army's only cargo helicopter, to get all of their missions and tasks done. As such, CABs had to remain flexible in their formations. Additional

1255 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

challenges range from meteorological risks to a counterinsurgency-focused culture. However, Army Aviation will continue to play a vital role in future operations. As such, CABs must educate division and corps-sized headquarters on how best to utilize Army Aviation to shape the fight.[3]

Methodology

This monograph consists of three main sections. The initial section summarizes the relevant background of Army Aviation, the requirements involved with the move towards LSCO, and the current capability of the force to apply emerging doctrine. In the second section, a historical example of Army Aviation's transformation in the 1980s accounts for the significant change of Army operations doctrine to the AirLand Battle construct. This section includes analysis of Army Aviation roles in Operations Desert Storm and Desert Shield, evaluated using three key elements of operational art: operational reach, tempo, and risk. The third section provides analysis of the current gaps that exist between doctrinal requirements of Army Aviation and its current capability. This section also highlights the outlook for the next ten to fifteen years for Army Aviation, and the associated gaps that those advances could create or close. Lastly, this section provides proposed methods to meet any remaining gaps between requirements and capability within the branch.

Application of Operational Art in Army Aviation Doctrine

Operational Art has evolved alongside changes in technology and the incorporation of new battlefield domains into US Army doctrine. As described in *Army Doctrine Reference Publication (ADRP) 3-0*, *Operations*, operational art "requires creative vision, broad experience, and knowledge of capabilities, tactics, and techniques across multiple domains." Today's domains of cyber, space, electronic, and information present a significant challenge for officers maintaining the broad and creative vision as they are not as tangible as the traditional land, air,

[3] Blackmon, *Pale Horse*, 162.

1256 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

and maritime domains. The publication of *FM 3-0*, according to Lieutenant General Michael D. Lundy, provides the Army with "an expanded physical, virtual, cognitive, and temporal perspective for accounting for the multi-domain extended capabilities of friendly and threat forces." The Army strives to meet the challenges presented by the multi-domain concept and LSCO threats with new manuals appearing in 2017 alongside the current body of aviation doctrine. LSCO has become the measuring standard of future conflict on lethality and large-scale demands of Army training and capabilities. Army officers can apply operational art as they plan, prepare, execute, and assess current and future operations including LSCO. Three of the ten elements of operational art—tempo, operational reach, and risk—enable an assessment of aviation doctrine as applied by commanders and staffs.[4]

ADRP 3-0, Operations, defines tempo as "the relative speed and rhythm of military operations over time with respect to the enemy." In both cases, Army Aviation must control tempo when reacting to and assessing the urgent requests for support from ground forces and air components. The ability to keep the tempo at the optimal level requires both audacity and patience. High tempo only remains effective for so long before increasing the risk to the endurance of the mission. The increase in congested airspace due to the proliferation of UAS and lower operational ceiling will also increase tempo while pushing the limits of its optimal level. A commander must assess and apply operational art in the planning of missions while maintaining the tempo when necessary to avoid sacrificing the other elements of operational art such as operational reach and decisive points.[5]

1257 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Army Aviation enhances speed, flexibility, and lethality during US Army operations. Army Aviation helps maintain the tempo of the combat arms team through deep attacks, reconnaissance, close and security support, and air movements. Per *FM 3-04*, a successful attack contains "audacity, speed, concentration of combat power at the right time and place, violence of execution, simultaneity of joint fires with ground and air maneuver, and maximizing the element of surprise." The optimal tempo maximizes the element of surprise while patience creates the window for the concentration of combat power and the seamless rhythm of coordinated air-ground operations (AGO) for a successful mission. An operation in a deep area that is aligned with the Army's prior AirLand Battle construct and remains in accordance with the current *FM 3-04*, influences the tempo for the accompanying unified land operations.[6]

> Aviation operations in deep areas may include—
>
> Attacks to destroy, defeat, disrupt, divert or delay enemy forces or high-value capabilities that are out of friendly contact using manned-unmanned teaming (MUM-T) or independent UAS attack-reconnaissance operations.
>
> Reconnaissance operations by manned and/or unmanned aircraft (UA) to obtain combat information to answer priority intelligence requirements (PIR) on the terrain, enemy or civilian populations.
>
> Air assaults of conventional or special operations forces to seize an objective, destroy an enemy force, or capture or kill a high-value target.
>
> Infiltrations of conventional and special operations forces to recover isolated personnel, emplace sensors, conduct raids, establish special reconnaissance positions, or to conduct partisan linkup.
>
> Air movements of supplies and personnel to ground maneuver units operating decentralized in deep areas.[7]

These operational examples from *FM 3-04*, all involve setting a desired tempo by striking quickly and violently, thereby supporting the rhythm for the AGO to either follow or attack simultaneously. As US Army leaders shift their focus from COIN to LSCO, their need increases

[6] US Department of the Army, *Field Manual (FM) 3-04, Army Aviation* (Washington, DC: Government Printing Office, 2015), 3-14, 1-1.

[7] US Army, *FM 3-04,* 1-39.

1258 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

to incorporate coordinated attacks across multiple domains to present the enemy with multiple dilemmas simultaneously. *ADP 3-0* describes the goal of these coordinated attacks: "degrade enemy freedom of action, reduce enemy flexibility and endurance, and upset enemy plans and coordination." This remains a challenge for commanders shifting focus to LSCO, as many have rarely attempted or trained for this type of coordinated attack. If the coordinated attack is successful it will enhance the US Army's tempo.[8]

Tempo is not only essential in attack missions but also crucial in reconnaissance missions. A commander's ability to make sound and accurate decisions rest on the timely and accurate flow of reconnaissance. Army Aviation has a responsibility to perform at the optimal tempo to meet the needs of intelligence and respond when the situation develops. Aviation meets this need through employment of MUM-T. The MUM-T ensures longer reconnaissance windows of up to forty hours and decreased gaps in intelligence coverage caused by crew changes. The longer reconnaissance windows and increased depth of reconnaissance and maneuver of UAS systems increase endurance and increased reconnaissance abilities require commanders to initiate and sustain the most advantageous tempo with AGOs. MUM-T hinders tempo in the management of UAS communication as they descend below coordinating altitude from restricted operations zones as depicted in Figure 1. MUM-T requires extra time and communication, but the advantages of the higher commander's situational awareness due to intelligence surveillance and reconnaissance outweigh the extra airspace control authority, planning, and coordination.[9]

1259 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

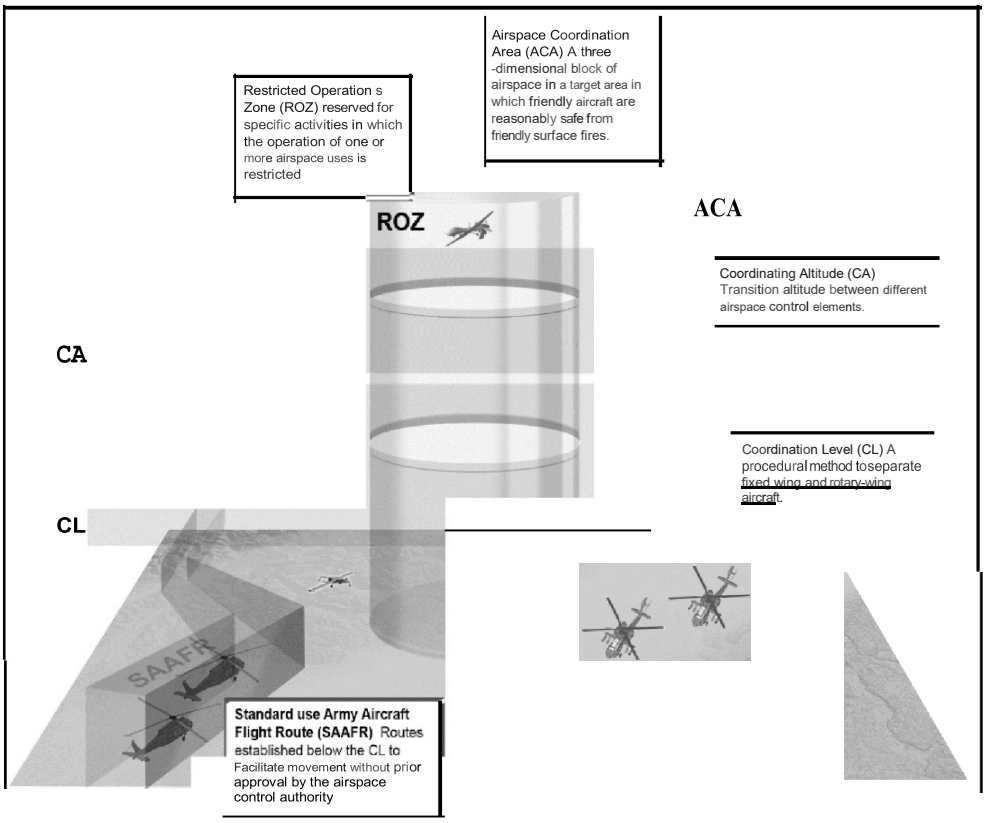

Figure 1. Common Army Airspace Coordinating Measures. *Field Manual (FM) 3-04, Army Aviation* 2015, 2-22.

Colonel Jimmy Blackmon has argued that recent COIN operations in Afghanistan and Iraq demonstrated that "the most underutilized collection assets were the rotary-wing aviation aircrews. Helicopters traverse and observe more of the brigade's battlespace daily than any other sensor on the battlefield." To keep the reconnaissance moving, all parties to include, UAS, pilots, and crews, whether lift or attack, need to be a part of the reconnaissance gathering as weather can prevent or limit employment of UAS and mission space does not always overlap. The US Army teaches soldiers to be critical thinkers. As one way to hone that skill, all aircrews should adopt a reconnaissance mindset.[10]

The tempo of the flow of reconnaissance is susceptible to disruption by many factors including natural and manmade, weather being the most prominent. Due to disruptions in

[10] Blackmon, *Pale Horse*, 58.

1260 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

reconnaissance "the commander must balance the time available versus the advantage of executing with tempo and surprise with the minimum mission essential information required to understand the friendly forces, terrain, weather and enemy forces to achieve success." Terrain can also limit the flow of reconnaissance because of visibility and poor communication. Additionally, the enemy will limit reconnaissance in LSCO through electronic warfare and their air defense systems. The last seventeen years of limited contingency operations have demonstrated that the experience gained while working in varied terrain, including mountains which limit line of sight, may reduce UAS range and data relay capability. Difficult weather patterns degrade communications between UAS and ground maneuver units, as do urban and desert terrain, as seen in Iraq and Afghanistan.[11]

The rhythm of the tempo created by the relationship between the air and ground forces is crucial to the success of the mission. The relationship takes time and practice to develop but, when the rhythm of AGOs is seamless, the mission success increases due to inherent flexibility and reaction time. Ideally, during COIN, CABs assigned specific task forces (TFs) to support a ground commander. This required pre-deployment training with the ground commander to establish habitual relationships with the CAB so that it could achieve its full potential. In this case, time permitted pre-deployment planning, but units might not have this luxury when a peer threat escalates quickly into LSCO. Integration of the CAB in air mission coordination meetings and air mission briefs increases awareness of effective ways to use Army Aviation. However, this remains difficult at the brigade level and proves even more of a challenge at the division and higher levels of command. The lack of rhythm of AGOs could also detract from the CAB's

[11] US Army, *FM 3-04*, 3-33; Charles K. Bartles and Lester W. Grau, *Mountain Warfare and Other Lofty Problems: Foreign Perspectives on High Altitude Combat* (West Midlands, England: Helion, 2016), 23; US Army, *FM 3-04*, 3-154; US Army, *ADP 3-0*, 15; Joshua Durham, "Testing the Army's Extended Range Gray Eagle UAS," *Army Aviation* (November 2018): 52-53.

1261 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

operational reach and increase risk until sound relationships develop and integration at the division level becomes routine.[12]

The second operational element routinely applied to Army Aviation is operational reach. *Joint Publication 3-0, Joint Operations,* defines operational reach as the "distance and duration across which a joint force can successfully employ military capabilities." The many changes in technology, new digital models of aircraft and MUM-T, have increased Army Aviation's length of optimal reach. Reach will play a pivotal role in Army Aviation's ability to shape the complex battlefield of LSCO. Army Aviation will need the ability to reach the centers of gravity to make the most impact on the conflict at hand. Difficulty could arise if a division, or above, does not understand how to effectively use Army Aviation's strengths, such as the potential reach of rotary wing operations or UAS, and therefore fails to integrate aviation effectively into their operations. The successful integration of MUM-T into a CAB can give commanders extended reach through continuous reconnaissance, current battle damage assessment, and contact with the enemy due to longer flight times of the Gray Eagle. The coordination of the UAS and AH-64 also extends reach for greater lethality by utilizing precision team targeting to give swift blows to high-payoff targets or against centers of gravity.[13]

Operational reach can be very critical to shaping operations as aviation's reach facilitates deep attacks. Aviation operational reach shapes the battlefield not only through deep attacks but also air assaults, and air movements. Placing critical supplies and soldiers where they will have the most impact on the battlefield extends the operational reach of the ground force to gain a position of relative advantage against threats that may outnumber US troops. Operational reach will be a critical element of any LSCO in order to keep the element of surprise, present multiple dilemmas simultaneously, disrupt troop reinforcements, and communications. The challenge is

[12] Blackmon, *Pale Horse*, 61; US Army, *FM 3-04*, 1-3.

[13] US Department of Defense, Joint Staff, *Joint Publication (JP) 3-0*, *Joint Operations* (Washington, DC: Government Printing Office, 2011), I-13; US Army, *FM 3-04*, 1-18.

1262 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Army Aviation's ability to meet the demands within the new doctrine, especially in LSCO against a peer threat.[14]

Army Aviation has seven core competencies, as seen below in Figure 2, and most apply to the operational reach of combat arms teams. Air assaults, in coordination with special operations forces (SOF) or other combined arms teams, can extend operational reach by quickly assembling battalions of troops for covert operations to cut off reinforcements or destroy centers of gravity that terrain would otherwise make impossible to reach. Air movements performed by cargo and utility aircraft also support operational reach of combined arms teams, especially when overcoming effects of terrain or enemy forces in isolated locations only accessible by rotary wing aircraft. Air movements can be inefficient compared to transporting heavy supplies and equipment by plane and therefore US forces utilize air movements when terrain or emergency necessitates the use. CABs arrange air movements by priority because of the smaller number of CH-47s assigned to CABs as seen below in Figure 3.[15]

The seven core competencies of Army Aviation are:

- Provide accurate and timely information collection on the enemy, terrain, local populations and friendly forces.
- Provide reaction time and maneuver space.
- Destroy, defeat, disrupt, divert, or delay enemy forces.
- Air assault ground maneuver forces.
- Air move personnel, equipment, and supplies.
- Evacuate wounded or recover isolated personnel.
- Enable mission command over extended ranges and complex terrain.

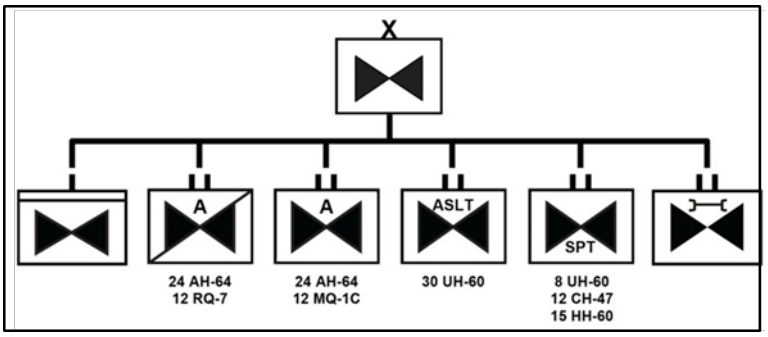

Figure 3. Combat Aviation Brigade. *Field Manual (FM) 3-04, Army Aviation* 2015, 2-2.

The third element of operational art that enables an assessment of Army Aviation doctrine is risk. LSCO presents a new demand on Army Aviation and will likely increase the risk of every mission. One of the demands of LSCO is the requirement of a CAB to retain flexibility within their formations. Formations may require tailored packages for different aircraft to facilitate different missions. The CAB contains finite resources and depending how LSCO unfolds it will be necessary to adjust formations to meet the demand of the ground force commander. This is like current COIN operations. However, it is likely the CAB must gain proficiency at adjusting frequently, where currently, they generally remain task organized for the duration of a deployment. Risk is inherent to all military operations. Commanders that are willing to incur a reasonable level of risk typically find it is "the key to exposing enemy weakness that the enemy considers beyond friendly reach."[16]

To mitigate risk, aviation commanders should—

Use the minimal security force required to gain contact while accomplishing the mission within the allotted time.

Maximize the use of UAS forward to provide reaction time and maneuver space.

Provide subordinates with control measures for not only their own areas of operations but also adjacent areas of operations to control and deconflict maneuver and fires.

Develop and coordinate air coordination measures to enable freedom of action of manned and unmanned systems.

[16] US Army, *ADRP 3-0*, 2-61; US Army, *FM 3-04*, 3-127-128; Blackmon, *Pale Horse,* 128.

1264 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Plan and employ joint fires through the depth of the zone.

Employ communications relay packages, Army Airborne Command and Control System or Airborne Battle Command Console aircraft to maintain communications over extended distances.

Position FARPs, UAS launch locations, and holding areas (HAs) forward to enable rapid turns of combat power once enemy contact is gained.

And most importantly, use speed and audacity to develop the situation upon gaining contact.[17]

While it is important to find ways to mitigate risks like those listed above when applying operational art of the ends, ways, and means, it is also crucial to account for the level of risk and risk limits of a potential enemy. When attacking from multiple domains it can increase the risk taken by the CAB, as well as increase the threat to the enemy and their level of risk. Risk is unavoidable, but navigating aviation operations and AGOs, a commander must strike a balance between acceptable risk and expected gains. Ways to mitigate such risks are maintaining flexibility within plans, planning thoroughly for missions, and establishing a good relationship between air and ground forces.[18]

Commanders need to be flexible in their planning of AGOs. Flexibility comes from retaining options, a position influenced by training and experience. Aviators can pull from their experiences as well as the experiences of others to create a flexible plan to account for different variables. The challenge with LSCO is the unfamiliarity of current aviation crews with such operations and the finite resources of a CAB to manage the demands of LSCO. Units need to have adaptable plans to react to the evolving circumstances in LSCO. Training, especially in coordination with the ground forces and integration at division level and above, can give the force an edge and foster flexibility by providing additional repetitions in exercises. Another technique to gain flexibility is to strive for habitual relationships between air and ground units.

[17] US Army, *FM 3-04*, 3-10.

[18] US Army, *ADP 3-0*, 23, 38; US Army, *FM 3-04*, 3-20.

1265 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Habitual relationships between air and ground units are ideal, but are often unattainable for varied reasons. It takes time and repetitions to cultivate such relationships. Given current demands, it is difficult to find the time to foster such relationships, and in a future LSCO it is doubtful there will be training time to build a relationship that does not exist. *FM 3-04*, operation doctrine refers to "hasty attacks in support of all friendly ground units regardless of their training level or habitual relationship, but with greater risk" as undesired, but this may become more common in future LSCO. Aviation doctrine teaches standardized procedures to reduce the risk of non-habitual relationships. Aviators must remain flexible and adaptive as Army Aviation moves forward into LSCO, to learn and mitigate risks to missions.[19]

One way to counterbalance the risks presented by a limited relationship with ground forces and experience is with reliable intelligence from reconnaissance. Reconnaissance mitigates risk by filling in the missing pieces of critical information, allowing commanders to make more informed decisions without jeopardizing the tempo of the mission set by waiting for the minimum critical mission information. Commanders require quick and reliable intelligence to be able to make bold decisions without large unnecessary risks, especially when having to coordinate and consider multiple domains in LSCO. The incorporation of MUM-T enables detection, consistent contact of enemy forces, and identification of high-payoff targets in a dynamic operating environment. MUM-T therefore provides flexibility as well as essential information which enables commanders to adjust their plans accordingly, while more accurately assessing risk. There is a potential risk in reliance on UAS, as other factors such as weather, or terrain, or the enemy's abilities may limit reconnaissance.[20]

Risk will always be a factor in operations, but it is the way aviators account and react to risk which ensures a successful mission. Aviators must strive to use and create a diverse

[19] US Army, *ADP 3-0*, 44; US Army, *FM 3-04*, 1-3.

[20] US Army, *FM 3-04*, 3-33, 3-40, 3-71, 3-154.

1266 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

knowledge base through training and experience to remain flexible in a complex mission environment such as LSCO. Combined arms teams must use the time they have together to train and create a quality learning environment, to standardize training objectives and mutual goals of the combined arms team.

Operational art "requires creative vision, broad experience, and knowledge of capabilities, tactics, and techniques across multiple domains." A future LSCO with a peer threat will stretch the US Army's current knowledge and capabilities. LSCO will require Army Aviation to provide the commander options to maneuver and position forces in a manner to best achieve their concept of operations. Army Aviation will meet the commander's need by leveraging their current doctrine to balance operational reach, tempo, and risk.[21]

Historical Case Study: Gulf War

The Gulf War, Desert Shield, and Desert Storm, illustrated the incorporation of operational art into AirLand Battle doctrine. According to author Robert Scales, AirLand Battle's "four tenets, initiative, agility, depth, and synchronization, are timeless, immutable precepts for present and future wars" as seen in unified land operations today. This historical case study will analyze how AirLand Battle and other Army doctrine applies to a near-peer threat in a short LSCO (in comparison to other LSCO like World War II). The three sections of operational art discussed in the doctrine portions: operational reach, tempo, and risk, are the basis for analysis of the historical case study.[22]

Background

In 1990, many evaluated the Iraqi Army as a near-peer threat to the US Army as Iraq had the fourth largest standing Army in the world. The livelihood of the Middle Eastern countries in

[21] US Army, *ADP 3-0*, 26.

1267 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

1990 was oil production and Kuwait, even though small, was an oil-rich country. During the 1980s many countries, such as Saudi Arabia and Iraq, had negative returns from their oil industry. In contrast, Kuwait maintained a positive income from oil. During this time the organization of the petroleum exporting countries made agreements to reduce oil production to increase the cost of oil. Kuwait, along with Saudi Arabia, increased their production. The price per barrel reached a low of fourteen dollars in June of 1990. Saddam Hussein, Iraqi President, was concerned about increased oil output in Kuwait and Saudi Arabia. President Hussein also feared Kuwait's western leaning intentions. The size of Iraq's army increased due to the war with Iran from 1980 to 1988 but left their treasury depleted, and Hussein looked toward Kuwait as a "quick fix" for their financial troubles.[23]

Hussein took drastic measures in August of 1990 and invaded Kuwait to seize Kuwaiti oil platforms to bolster Iraq's own oil production. After the invasion, Hussein claimed that western foreigners had annexed Kuwait from Iraq after World War II and claimed Kuwait as the nineteenth province of Iraq. The United States and its allies responded with diplomatic solutions with the United Nations. While diplomatic channels were working, the United States with Saudi Arabia, set up a "line in the sand" near the border of Saudi Arabia and Kuwait. This was the start of Operation Desert Shield, which also afforded the train up prior to Desert Storm. Near the border, the United States and Saudi Arabia built up forces while training troops, and conducting exercises with aircraft and live fire munitions. Army Aviation conducted screening along the border to provide reconnaissance on Iraqi troop movements as an early warning system, and set

up forward operating bases (FOBs) near the Saudi Arabian and Kuwaiti border. The buildup of troops in Saudi Arabia was enough to deter Saddam Hussein from invading the country; a fear held by King Fahd of Saudi Arabia.[24]

Desert Shield Analysis

Desert Storm's high-speed air and ground offense often overshadows Desert Shield's contribution to the Gulf War. Desert Shield was a necessary step that paved the way for the success of Desert Storm. The planning, training, and rehearsal time for Desert Storm was unprecedented. In past conflicts, the escalation to war with little intelligence "meant that first battles proved to be bloody schools in which green staffs and units were obliged to refine their skills on the battlefield." The training time afforded during Desert Shield gave not only US Army Aviation time to train the desert terrain, but also afforded time to develop joint relationships with sister services to "avoid another instance of learning in combat what the services could have practiced in pre-war training."[25]

Lieutenant Colonel Dell Dailey's 3-160th conducted a joint exercise that mitigated risk and cultivated relationships between the services by incorporating Navy, Marine, and Air Force pilots practicing combat search and rescue (CSAR). Colonel Jesse Johnson of Special Operations Command-Central (SOCCENT), oversaw all CSAR operations in Kuwait, Iraq, and twelve miles out into the gulf as SOF had the most experienced crews and best equipped aircraft for deep insertions. If available, Lieutenant Colonel Dailey fielded most of the calls as he had taken

1269 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

measures to prepare his crews and build confidence in CSAR operations with sister services by creating CSAR scenarios in the deserts of Saudi Arabia during Desert Shield. Lieutenant Colonel Dailey dropped the Navy, Air Force, and Marine pilots in the desert at night, and then recovered them through extraction. This training was beneficial for those dropped off as it enhanced their survival, evasion, resistance, and escape (SERE) training for the pilots, then have his crews come in low and fast for a night extraction. By using the time of Desert Shield for training CSAR operations, Lieutenant Colonel Dailey was able to minimize risk, maximize tempo as crews were familiar with conducting night CSAR operations. Therefore, his pilots needed minimal planning as they were well trained. The incorporation of the other services' pilots fostered relationships across the services which facilitated the tempo of Desert Storm as the crews conducted close air support and deep attacks in concert.[26]

The risk was still present even for the more experienced SOF pilots and crews. SOCCENT had to determine, with every call, if it was an acceptable risk to expose aircraft and crews to danger to conduct CSAR operations. The SOF pilots had trained for CSAR operations and were better prepared for the risky situation of a hot landing zone. The 229th Attack Helicopter Battalion from Fort Rucker, Alabama, did not undergo the same training as the SOF pilots. A UH-60 from 2-229th attempted a CSAR operation, for a downed Air Force F-16 pilot, when SOF was not available and the enemy shot the UH-60 down. Only three of the seven CSAR missions throughout Desert Storm were successful. The SOF crews, who had received the extra training, flew all the successful CSARs. The specialized training of the SOF pilots and crews mitigated risk and allowed the crews to reach deep into enemy territory.[27]

Forces maintained operational tempo during Desert Storm because of the training performed during Desert Shield. The XVIII Airborne Commander, General Gary Luck, described

[26] Scales, *Certain Victory,* 195-198.

[27] Scales, *Certain Victory*, 195.

1270 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

it as "actually the best training we've probably ever had in this Army because of the resources and space put at our disposal." General Luck set up training areas and firing ranges to sharpen combat skills and to adjust to the desert climate and challenges. The AirLand Battle defines agility as "the ability of friendly forces to act faster than the enemy, [which] is the first prerequisite for seizing and holding the initiative." Desert Shield's training facilitated the agility demonstrated by forces upon the execution of Desert Storm.[28]

General Luck and XVIII Airborne Corps used AirLand Battle's tenet of agility by disseminating lessons learned from Desert Shield to combat risk while facilitating tempo. Pamphlets and handbooks circulated through department of the Army staff and US Army Training and Doctrine Command to share the knowledge of hard-learned lessons in the desert through official channels. This information and lessons learned greatly increased the incoming units learning curve for operating in the desert. As an example, initially, the AH-64 encountered issues with "losing control of the Hellfire caused by laser backscatter from the fine sand suspended in the air." AH-64 crews solved the issue before executing their deep attack mission in support of Operation Desert Storm and disseminated the lessons to adjacent and incoming units.[29]

Task Force Normandy

"One of the smallest yet most successful and important Joint-Army-Air Force operations in the initial strikes in Operation Desert Storm was Task Force Normandy." The TF consisted of eight Army AH-64 Apaches and four Air Force MH-53 Pave Low helicopters. The TF conducted a deep attack into Iraq to destroy two early warning sites to blind the Iraqi's air defense system prior to commencing the air campaign. US forces had to destroy the early warning sites simultaneously to avoid alerting the air defense system. TF Normandy meticulously planned and conducted many rehearsals to mitigate risk during their deep attack. This resulted in successfully

[28] First quote from Scales, *Certain Victory*, 151; second quote from Ward, *The Division Artillery*, 95; Scales, *Certain Victory*, 151

[29] Scales, *Certain Victory*, 151.

1271 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

blinding the Iraqis and serves as an example of operational reach and synchronization within AirLand Battle doctrine.[30]

"Deep operations require boldness and audacity and yet carry an element of risk due to overextension." TF Normandy assumed many risks besides conducting a deep attack into Iraq at night while flying nap of the earth. The teams trained for three months developing the habitual relationships necessary because "between inter-service aircrews there was a natural and mutual mistrust within the aviation community" and finding solutions to the different equipment needs, tactics, training, and procedures. As General Donn A. Starry accurately said, "deep attack is not a luxury; it is an absolute necessity to winning." Despite the higher risk, the United States approved TF Normandy to commence the attack against the two targets as seen below in Figure 4. The TF gained approval because of their training, proven synchronization, and necessity of the mission to blind the Iraqi air defense.[31]

[30] Williams, *A History of Army Aviation*, 246; Scales, *Certain Victory*, 158-159; Paul E. Berg and Kenneth E. Figure 4. AH 64 Apache Attack on Iraqi Radar Sites. "Task Force Normandy," 141.

To reach twenty miles deep into Iraqi territory a great debate arose for the best aircraft and team for the mission. The qualifications came down to those discussed in AirLand Battle, "using speed, maneuver and firepower that is both precise and massive." The AH-64s had the speed and most accurate and massive firepower but were lacking in their ability to maneuver at night. The Air Force MH-53s did not have adequate firepower to conduct the attack, but did have the global positioning system capabilities that the AH-64 lacked. Therefore, the MH-53s lead them to a designated separation point. The deep attack was only possible using both airframes working together. Additionally, UH-60s in proximity with AH-64 mechanics were on hand to quickly react to downed or damaged aircraft. The timing and tempo of Desert Shield allowed the TF to focus on preparing their mission. The three months of training afforded them the time to solve problems such as chemical lights to mark the designated release points and limited reach of the AH-64 by switching out a rocket pod and replacing with an external fuel tank. The

1273 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

synchronization set the smooth tempo of TF Normandy as a "maximum economy of force, with every resource used where and when it will make the greatest contribution to success so that nothing is wasted or overlooked."[32]

Forward Operating Base Cobra and Air Assault to Highway 8

The establishment of FOB Cobra and the air assault to Highway 8 tested the tempo and synchronization of the 101st Airborne Division. General James Henry Binford Peay III had assembled six kilometers to the south of the Iraqi border "the largest air armada the United States had ever committed to a single air assault operation." AH-64 Apaches led a scouting party, and escorted the sixty-six UH-60 Blackhawks and thirty CH-47 Chinooks. The air assault transported the first 500 soldiers as well as sling loaded howitzers and high mobility multipurpose wheeled vehicle (HMMWV) 110 miles into Iraq to set up FOB Cobra for the next stage in the air assault, cutting off the Iraqi supply line on Highway 8 along the Euphrates River as seen in Figure 5 below. This risky air assault served as an excellent example of the use of an air assault to reach deep into enemy territory and disrupt lines of reinforcement and supply.[33]

[32] First quote from Houland, *Gulf War,*109; second quote from Scales, *Certain Victory*, 107; Berg and Tilley, "Task Force Normandy," 142-144; Scales, *Certain Victory,* 157.

1274 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

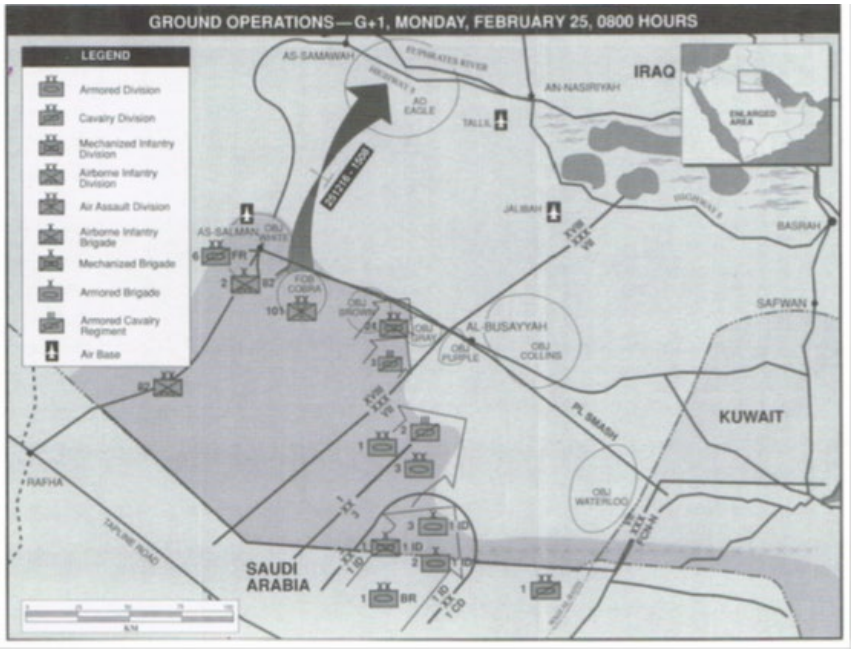

Figure 5. Ground Operations-G+1, Monday, February 25. *Certain Victory*, 304.

The air assault required intense planning as it required three turns to lift the whole brigade. The AH-64 Apaches and AH-1 Cobras scouted for possible enemy threats around FOB Cobra to maintain the FOB's security. The AH-1s discovered an Iraqi infantry battalion dug into the ridge along the east-west road. After discovery, the AH-1 crews landed and conferred with Infantry Company Commander Captain John Russell to establish friendly positions and plan of action. The size of the enemy footprint required support from Air Force A-10s. Fortunately, there was an embedded Air Force liaison officer with the Air Force unit. This enabled the force to maintain their tempo by quickly creating a Joint Air Attack Team of Air Force A-10s and Army Cobras and Apaches. The Joint Air Attack Team bombarded the Iraqi position, leading to 340 Iraqis surrendering, securing FOB Cobra, and providing mission security of the air assault to Highway 8.[34]

[34] Scales, *Certain Victory*, 219; Murray, *Air War in the Persian Gulf*, 277; 101st Airborne Division, "After Action Report Operation Desert Shield/Desert Storm" (Command Report, 13 June 1991), 45-47.

1275 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Once the fifteen kilometers perimeter around FOB Cobra was secure, the next part of the mission began with the 101st and 229th Attack Helicopter Battalion AH-64s scouting landing zones and enemy near Highway 8. The 229th Attack Helicopter Battalion augmented 101st, providing flexibility to the CAB to conduct their deep attack mission. The reconnaissance and escort for UH-60 Blackhawks was crucial to the success of the deep insertions of long-range surveillance detachments. The weather changed to rain and therefore the AH-64 reconnaissance teams had to determine the available landing zones that were suitable for the air assaulting soldiers and vehicles as seen in Figure 6 below. The reconnaissance and long-range survival detachment maintained the tempo for the mission and mitigated risk of delay due to weather.[35]

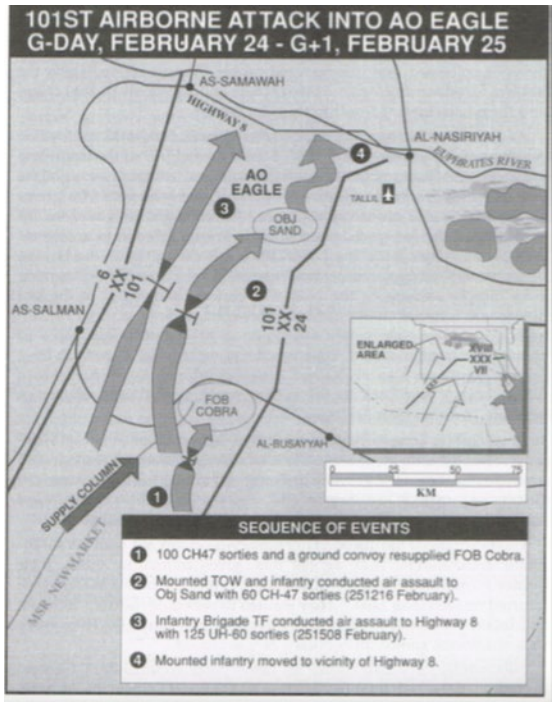

Figure 6. 101st Airborne Attack into AO Eagle. *Certain Victory*, 221.

The next step was the two-prong insertion of an infantry division and anti-armor, supply, and communication vehicles. The AH64 reconnaissance mission on landing zones enabled sixty UH-60s to insert the first 500 infantry soldiers into unobstructed landing zones adjacent to

Highway 8. In just thirty-one hours, in a bold and quick deep attack, the 101st had cut off "the key Iraqi Basrah-Baghdad lifeline." All four of the tenets of AirLand Battle doctrine; initiative, agility, depth, and synchronization, were a part of the air assault to Highway 8. The air assault was bold and risky, however, the 101st mitigated the risk through reconnaissance and building up to this assault with other, smaller assaults.[36]

Pre-Ground Day Raids

Before the start of the hundred-hour ground war, Army Aviation played a key role in shaping the battlefield with pre-ground day raids and feints that contributed to the success of the "great wheel." The pre-ground day raids served a dual purpose of interdicting the enemy's supply depots, surveillance posts, armored vehicles, antiaircraft positions, and securing the main supply routes. The second purpose was training for future deep attacks in a lower risk environment and building relationships with armor and infantry divisions that would prove crucial during the ground war.[37]

The biggest feint in the pre-ground day raids involved the VII Corps artillery and the AH-64 from the 11th Aviation Brigade serving as "a carefully rehearsed drill for later deep attacks." Generals Tommy Franks and Robert Abrams observed the feint from the artillery command post to pinpoint any improvements before future riskier deep attacks of the ground war. The pre-raids mitigated a lot of the risk by providing training, reviewing opportunities, and ensuring main supply routes were clear, which are crucial to support aviation missions. "Fuel is the lifeblood" of aviation, as an attack helicopter can burn an average of two and half gallons per minute. Without sufficient and well-placed refueling points, aviation's tempo is severely hindered.[38]

1277 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The pre-Ground Day raids not only opened main supply routes Texas and Newmarket, but lead to several Iraqi units to surrender. Aviation also teamed up with the Psychological Warfare Military Intelligence Battalion to use loudspeakers attached to some Blackhawks and drop leaflets to coax the Iraqis out of the bombarded bunkers, as seen in Figure 7 below. The 101st, with coordination of 187th Infantry, recovered 406 prisoners when they secured the site. Intel recovered from the site, along with information gained by debriefing the prisoners, benefited the planning of future deep attacks. The synchronization with psychological warfare and infantry battalions, allowed the combined arms team to utilize the strengths of many different branches to create an optimal tempo of mission and foster success.[39]

Figure 7. Psychological Warfare with a UH-60. *Certain Victory*, 199.

Concluding Analysis of Gulf War

The Gulf War comprised of Desert Shield and Storm lent itself very well to AirLand Battle doctrine. Iraq had a large army, but they were not well trained, and many of their resources were outdated. The transparent outline of Iraq's capabilities and weaponry acquired in a recent long war with Iran, allowed the United States to adequately prepare to counter and overmatch the threats posed by Iraq. Desert Shield also proved as a training ground for future missions, such as TF Normandy and the 101st air assault to Highway 8. The training time gained during Desert

[39] Scales, *Certain Victory*, 199-200.

1278 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Shield, and the feints during the Great Wheel, demonstrated the Army's operational reach and high tempo.

The amount of planning time afforded to Desert Shield and Desert Storm, while Saddam Hussein was stalling diplomatic sanctions, will likely be unavailable in LSCO. The buildup time to conflict could be significantly faster and would require swift reaction of US forces to mobilize in theater. Iraq was not a peer threat and did not have the advantage of observing the United States implement the AH-64 and other new technologies before the Gulf War. Our current competitors and adversaries have observed the US in seventeen years of COIN and have observed how the United States fights, implements its technologies, and reacts to changes on the battlefield. New airframes, such as new UAS systems or future vertical lift platforms, must prove themselves effective in LSCO, just like the AH-64 did in Desert Storm. The proliferation of technology and multi-domain theaters will create more of a challenge for Army Aviation than in Desert Shield and Desert Storm. The timeless tenets of AirLand Battle doctrine are still current for a contemporary LSCO. In a current day LSCO Army Aviation needs to maintain a high tempo, long operational reach, and react quickly when a multi-domain window of opportunity opens.

Gaps and Recommendations for Future Army Aviation

Large Scale Combat Operations in a multi-domain environment is a drastic change from the last seventeen years of COIN. The culture of the Army evolved from fighting decentralized in brigades and now towards headquarters seen as the resource integrator, versus a resource provider. Changing the culture will take time, especially while the Army handles additional gaps in doctrine, training, and capabilities. World conflict will not wait for such an evolution in Army culture. The echelon above brigade (EAB) must be well organized and able to decongest a complex battlefield, to pinpoint the areas of convergence and dis-integrate them. Unlike the historical case study, potential adversaries can contest the airspace and match US air superiority. One of Army Aviation's main roles discussed in this paper is the capability to reach deep into

1279 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

contested areas, such as in the case study with TF Normandy and the 101st air assault to Highway 8.[40]

In the current operational environment, our adversaries have developed air defense systems to deny Army Aviation's freedom of maneuver in multi-domain operations (MDO). Unfortunately, it is not only an air defense system, but the Anti-Access/Area Denial (A2/AD) contesting many of the domains. The A2/AD system, depicted in Figure 8 below, illustrates the United States' peer threats A2/AD system. Russia and China have shared some of their A2/AD systems with other countries, which then serve as a testing ground of the A2/AD systems. The United States will be able to find weaknesses in the systems, and at the same time Russia and China will be watching to address those weaknesses in their A2/AD systems.[41]

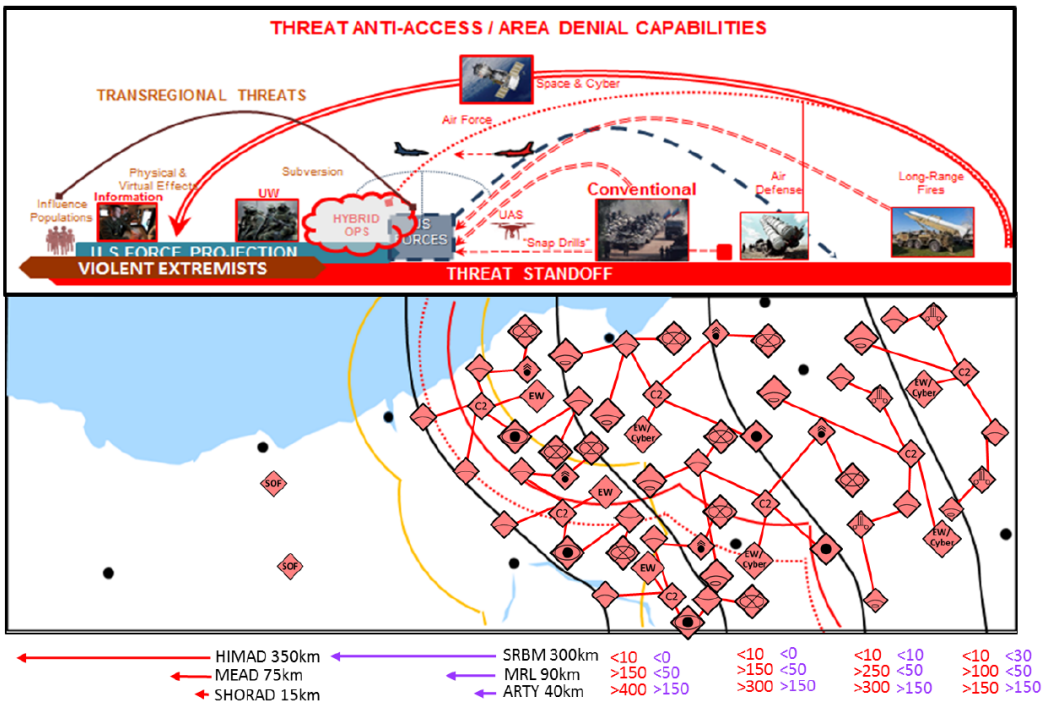

Figure 8. Threat Anti-Access/Area Denial Capabilities. *TRADOC Pamphlet 525-3-8*, 36.

Army Aviation will switch their focus to employ multiple cross-domain maneuvers designed by EAB to create windows of opportunity for maneuver forces. To achieve overmatch when facing a peer-adversary, Army Aviation must have the capability to reach, provide close air support, lethality, and situational understanding. For the consideration of this paper, the focus will be the gaps in capability to reach and play a crucial role in AGOs and ensuring freedom of maneuver. The second part of this discussion will analyze the training gaps for current and future Army Aviators, as well as EAB, to successfully utilize the asymmetric advantages that Army Aviation provides in LSCO.[42]

Reach: Range, Speed, Survivability, and Maneuverability

According to Army Aviation's equipment modernization strategy, reach is a part of the first four of seven key Army Aviation challenges and gaps, as identified in the Army's capability

[42] US Department of the Army, *TRADOC Pamphlet 525-3-8, The US Army Concept for Multi-Domain Combined Arms Operations at Echelons Above Brigade 2015-2045* (Fort Eustis, VA: Government Printing Office, 2018), 6.

1281 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

needs analysis. Army Aviation requires platforms to have adequate range, speed, survivability, maneuverability, and deploy quickly to strategic locations with little notice. Two of the major differences between COIN and LSCO are going to be the theater and availability of troops and divisions already on the ground, such as our contingent in Iraq and Afghanistan. Regarding LSCO, the theater could be immense and the range of UAS platforms could fall short of intelligence, surveillance, and reconnaissance requirements. The United States would have to project into an undeveloped theater and fight to gain a foothold, unlike the last seventeen years. The Apache AH-64D/E currently has lower combat range and cruise speed than the assault and air movement airframes.[43]

The deficient range capability of the AH-64 is priority number six out of sixty-seven high-priority programs for the Army fiscal year 2019 budget. The Army's improved turbine engine program attempts to resolve this shortfall, and intends to expand the program to the UH-60M. This program seeks improved fuel consumption and greater power to support increased maneuverability. Given the importance of range to aviation operations, the Army recently took great lengths to test the Army's range of the UAS MQ-1C extended range. The extended range Gray Eagle underwent an extensive fourty-two day training mission with F Company from 160th Special Operations Aviation Regiment Airborne (SOAR) at the National Training Center (NTC) in Fort Irwin, California. The MQ-1C extended range satisfied the demand for a combat radius of 1,000 kilometers and fourteen hours of loitering time. It also set the standard of forty hours of continuous flight with a common sensor payload and twenty-four hours with a payload of two Hellfire missiles. Army Aviation is making attempts to fill capability gaps, but it takes valuable

1282 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

time, and money as the MQ-1C Extended Range three-year project cost over thirteen million dollars but met with success.[44]

Future Vertical Lift (FVL) works toward improving future airframes with greater range, power, and sustainability. FVL, elevated into one of the six cross-functional teams in the new modernization strategy of the Army, as seen below in table 1. The new lines of effort are the future attack-reconnaissance aircraft, the future long-range assault aircraft, an advanced UAS, and a modular system approach. The challenge facing FVL is creating strategies and procuring technology to defeat (or make small windows of opportunity against) A2/AD systems as seen below in Figure 9. Another capability gap is the susceptibility of cyber-attack. FVL is working on implementing a "digital backbone that affords a cyberphysical interface" to not only protect, but enable quick, fleet wide updates to be proactive against an emerging threat. The capability to implement updates to current systems is usually a long process, but that will soon change with the installment of the CAB architecture integration lab. The Army does not have rights to most of the software on the aircraft, and any improvements or additions must go back to the manufacturing company for testing and approval. This is a timely and costly process. The UH-60V will be the first aircraft with the open systems architecture mission computer. The Army will own the rights to the software and rapidly speed up the process of new technology insertions in the refurbished UH-60L.[45]

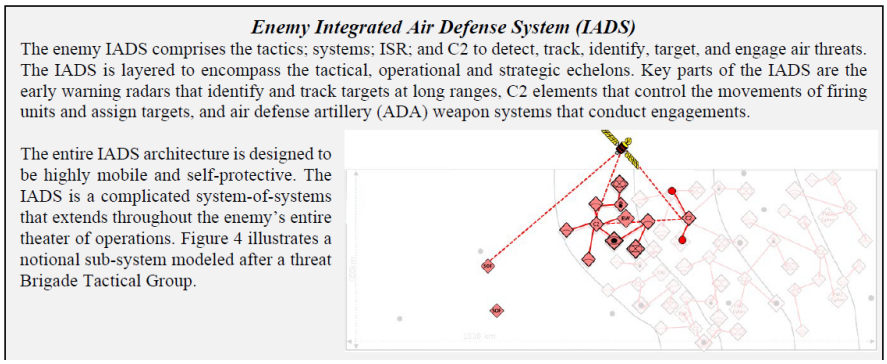

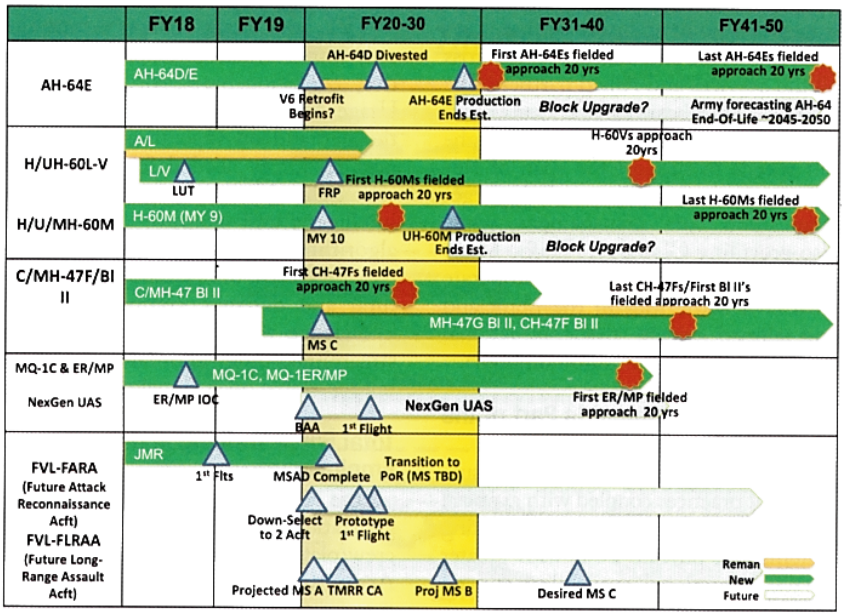

Figure 9. Enemy Integrated Air Defense System. *TRADOC Pamphlet 525-3-8*, 42.

FVL's challenge is the task of making the expeditionary aviation forces self-deployable, by increasing their range, as well as maintenance requirements. Several units that stand at the ready for deployment of large distances into US Indo-Pacific Command rely heavily on C17's for transport. The transportation issues arise at the low supply of C17's to mobilize CH-47s, UH-60s, AH-64s, and UAS. A C-17 can only take one CH-47 at a time, or two UH-60s, and that is after units have prepared the aircraft for transportation in the C-17. Upon landing, units must conduct hours of maintenance and test flights. It can take several weeks to mobilize just an aviation expeditionary force, which is not quick enough for mobilization in support of LSCO. Once the expeditionary forces mobilize, they need the flexibility of movement, which is typically dependent on sustainment. Aviation is reaching a pivotal point in the modernization of the fleet

1284 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

with investing in the legacy airframes to ensure readiness to fight LSCO today, versus the future fleet with upgraded capabilities. As seen below in table 2, the modernization chart has most of the legacy fleet in service until fiscal year 2050. The CH-47F, with the digital cockpit upgrades, cost the aircraft 4,000 pounds of payload. Army Aviation is attempting to regain the 4,000 pounds of capability through engine and rotor blade enhancements. The Army can only upgrade the legacy fleet to a certain point, as seen with the CH-47, and aviation must balance when to invest in new models over modifying the current fleet. The Army has the largest vertical fleet of the service, yet only spent twenty-seven and a half percent of the total military services rotary wing aviation spending on research and development. The Army needs to find a balance between sustaining the legacy fleet and investing in FVL.[46]

Table 2. Army Aviation Major Fleet Modernization Perspective

Sustainment

FVL's future goals include maintenance free intervals of their platforms for thirty days or sixty hours. Sergeant Major Mike Dove, Command Sergeant Major of Army Aviation and Missile Command (AMCOM) Life Cycle Management Command (LCMC), commented on the maintenance intervals as "a lofty goal" during the Cribbins Aviation product sustainment symposium, but later compared them to the commercial airline fleet maintenance schedule. Though it has not been much of a concern the last seventeen years in COIN, Army Aviation maintenance capability is a major concern for LSCO. Units delegated aircraft reset to contractors during COIN, along with other maintenance duties, but that may not be possible during LSCO. Army maintenance companies are now returning to completing phase inspections to gain battle readiness again, but it will take time and initiative in each division to wean maintenance companies off a strong contractor's presence. The reset program, now a part of CAB responsibility has undergone a new concept to rate aircraft reset needs based on a holistic approach of the aircraft, as seen in Figure 10, instead of just deployment cycle. The sustainment decision support tool makes the process more efficient, and takes into consideration more factors, such as operational tempo.[47]

Hudson and John Gipson, "1ID CAB Aviation Maintenance in a Post-ARFORGEN World," *Army Aviation* (January 2019): 42-43; Shawn T. Prickett and James P. Snyder, "Sustaining the Fleet–Leveraging Condition Based Reset," *Army Aviation* (January 2019): 36-37.

1286 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

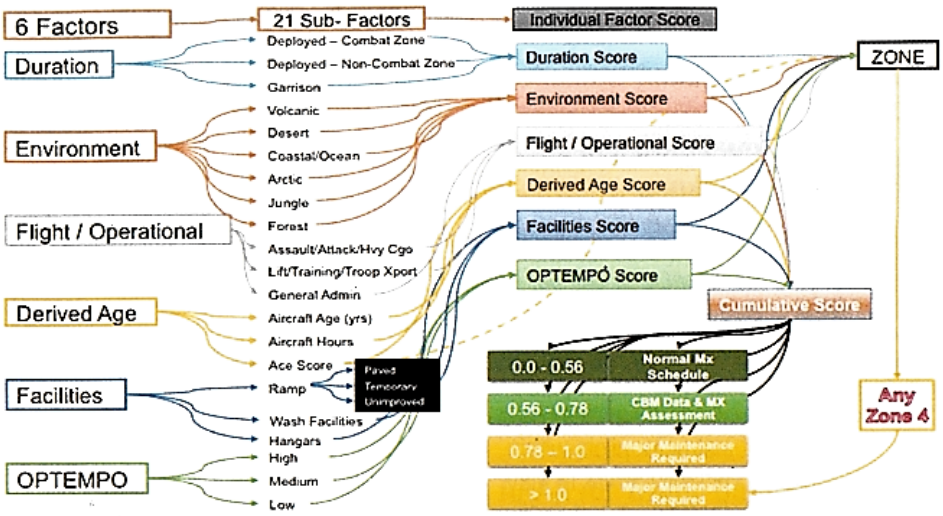

Figure 10. Condition Based Decision Support Tool Factors. "Sustaining the Fleet," 36.

A peer threat can target the Army's center of gravity, mainly the supply chain and maintenance capabilities, limiting the Army's operational reach. Maintenance will have to be agile, organically mobile, and expeditionary, as shown in Figure 11 below, to avoid becoming an easy target. The same will also be true for aviation aircraft. The CAB must be able to operate while breaking up maintenance organizations into smaller formations in multiple locations. If broken down into platoons, the formations of aircraft will become less of a target and less of a risk to the CAB. LSCO could require maintenance mobility time frames of every twenty-four to forty-eight hours as the CAB maneuvers.[48]

[48] Prickett and Snyder, "Sustaining the Fleet," 36-37.

1287 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

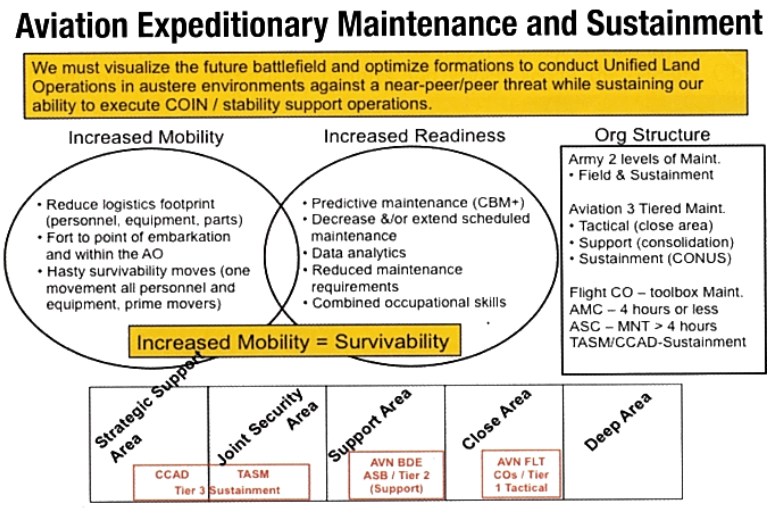

Figure 11. Aviation Expeditionary Maintenance and Sustainment. "Expeditionary Sustainment in Support of Large Scale Operations," 31.

AMCOM operated on the "Just-In-Time" inventory approach due to the logistics modernization program. The logistics modernization program focused on the most efficient method to keep the lowest possible stock on hand. The logistics modernization program was efficient and effective for Army Aviation's efforts in COIN, but represents another shock in Army culture in the change needed for fleet readiness of in-depth supply chains. The identified gaps in sustainment for LSCO, and goals set by AMCOM, includes ninety days of stock on hand with no backorder of more than thirty days for critical readiness parts. AMCOM identified the top readiness drivers as a priority for each aircraft to build enough supply depth. The question arises if AMCOM will be able to predict and anticipate the supply needs of LSCO, especially with the previous supply state of mind from the logistics modernization program, "Just in Time." AMCOM is setting the best goals, but LSCO is unknown. There are still capability gaps in the supply chain and formations of maintenance that need to adjust before the US engages in a conflict with near or peer threats. Maintenance is just one factor in the survivability of the aircraft.[49]

[49] David K Almquist and Brent Swart, "AMCOM-Working to Attain Strategic Supply Chain Depth," *Army Aviation* (October 2018): 56-57; Douglas M. Gabram, "Attacking Aviation Readiness Drivers," *Army Aviation* (October 2018): 11.

1288 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Another integral part of survivability of Army Aviation in LSCO is equipment, current technology, and strategy to defend against a near or peer threat. The project management office for aircraft survivability equipment (PMO ASE) is fielding many systems, such as the advanced threat infrared countermeasures for CH-47 aircraft, to defend against man-portable air-defense systems. The PMO ASE found success and continues to test new updated versions to include the AN/AVR-2B laser detecting set, a passive laser warning system to increase aircrew situational awareness. The capability gap of facing an A2/AD system is still an ongoing issue, as PMO ASE is still pursuing multi-spectral detect and defeat technology to outmatch our near and peer threats. The PMO ASE made small successes on the path to defending against A2/AD systems, but are not currently enough for LSCO.[50]

Training Gaps

The NTC at Fort Irwin, California works to revitalize their training to fit an MDO scenario for live training against a near-peer threat. The slogan used by NTC is "Ready now to win against a near-peer threat. Readiness for ground combat remains our number one priority." NTC pushes to increase the tempo, lethality, complexity, and limited communication of an MDO with a peer threat. NTC brought to light the lack of knowledge of efficient use of Army Aviation, especially the UAS. One of the many lessons learned of NTC is to "learn faster, and synchronize combined arms faster than the enemy." Fighting at echelon is difficult due to the complex synchronization, especially when units are unfamiliar with how to employ Army Aviation in LSCO. NTC is striving to provide realistic training. However, electronic warfare and cyber-attacks are not yet present, and as such, units lack repetitions on operating with such threats. NTC is only capable of providing a near-peer threat in terms of capabilities which was a large transition from COIN. If the purpose of NTC, according to the commander of operations at NTC,

[50] Kevin S. Chaney, "Project Manager Aircraft Survivability Update," *Army Aviation* (October 2018): 29-31.

1289 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Colonel Christopher R. Norrie, is to "ensure that units have their hardest day in the desert so that no soldier goes untrained into combat," then their ultimate goal should be to train against a peer threat instead of a near-peer threat.[51]

NTC's goal is not only to train the brigade, but also build up and train their leadership. One observation of Army Aviation made at NTC, was the diminished amount of platoon leaders serving as air mission commanders. CABs need to instill the younger officers with the experience they will need in mitigating risk, planning, and leading flight formations, and the burdens of mission success for the future company and battalion commands. Company commanders are the prime educators for their unit's air mission commander. If they lack in experience, it will reflect on the knowledge of the air mission commander. NTC is an excellent learning environment for young officers, but only if given the leadership roles that "will guarantee competent leaders and commanders at echelon that lead and fight in a complex environment," according to deputy commander of the Combat Readiness Center, COL Christopher Waters.[52]

The Joint Readiness Training Center (JRTC) has also been evolving its training techniques. JRTC focuses on the peer-threat faced by the United States in LSCO. JRTC expanded its training area in response to the break from COIN to mass combat capabilities and focus on combined arms integration. The fourteen-day crucible challenges brigades to integrate into the division level fight, not just at the brigade or battalion level. Similar to NTC, JRTC also needs to incorporate electronic warfare and cyber-attacks into training scenarios. The terrain of JRTC, although expanded, has little-improved roads to simulate urban conditions that will be a part of LSCO. The terrain does simulate lack of open areas as an urban environment would for massing

[51] First quote from Christopher R. Norrie, Thomas E. Lamb, and Michael J. Culler, "Ready Now-Our Number One Priority," *Military Review* (September-October 2018): 61; second quote from Norrie, Lamb, and Culler, "Ready Now-Our Number One Priority," 67; third quote from Norrie, Lamb, and Culler, "Ready Now-Our Number One Priority," 62.

1290 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

combat power but lacks the substantial noncombatant population challenge. JRTC is ever evolving and successfully breaking down the culture and norms established by the last seventeen years of COIN. JRTC is setting a foundation for fighting at EAB but still requires additional improvements to prepare units for LSCO by including electronic warfare, cyber warfare, and A2/AD.[53]

160th SOAR is trying to bridge the gap of tactics against defeating the A2/AD systems. SOAR identified the gap in training for advanced weaponry tactics compared to other sister aviation services, such as the Marine Corps' weapons and tactics instructor course, and the Air Force weapons school. SOAR is trying to solve the A2/AD threat and other challenges presented by an MDO by creating advancements in education and training. SOAR's motto is to "own the night," which without any changes and advancements will not be a given, as even SOF can no longer count on air superiority or unimpeded night operations. Figure 12 below demonstrates SOAR's vision for their tactics program. The vision is to fuse intelligence, electronic warfare, and Army Aviation Mission Survivability Officers (AMSO). The school will combine their expertise to enhance their crews' survivability. The key to fighting in an MDO is a combined effort to attack in multiple domains, but that is not possible without first establishing habitual relationships within the multiple domains.[54]

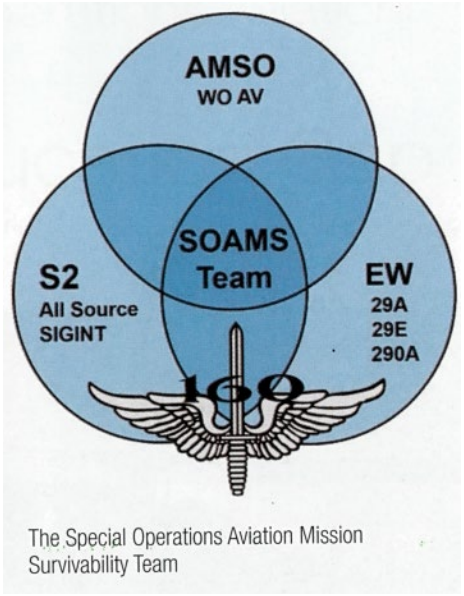

Figure 12. The Special Operations Mission Survivability Team. "Bridging the Aviation Education Gap," 28.

Mission command training program (MCTP) and the warfighter exercises observations are like the gaps observed by the 160th SOAR. The failure to integrate and synchronize resources degrade the efficiency of the AGO. The three main contributors to a failure of AGO at the warfighter exercises were "synchronization of operations in the deep area, integrated targeting at the division and higher level, and tasking and employment of the Gray Eagle UAS." The first and second issues are due to the decentralized mindset of a CAB from the many years of COIN. Headquarters must take an active role and integrate the CAB and artillery to ensure mission success. The third is concerning with misuse of UAS. UAS has so many capabilities, as seen in Figure 13 below, and division and corps must learn how to best utilize the UAS in multiple situations. The under or over utilization of Army Aviation at EAB is a concern for aviation. Vertical lift can be an asset by leveraging windows of opportunity for an AGO in an MDO, but only if used efficiently. The MCTP is working on training EABs to understand how to integrate the UAS, MUM-T, close support, air assaults, and deep attacks into their plans. The doctrine exists on how to employ MUM-T, but the training is still evolving to accomplish the guidelines set in *FM 3-04*. Flight school level and brigade level need new training simulators to incorporate

1292 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

UAS drivers and AH-64 teams to train together in a live virtual environment to develop the MUM-T relationships and familiarity.[55]

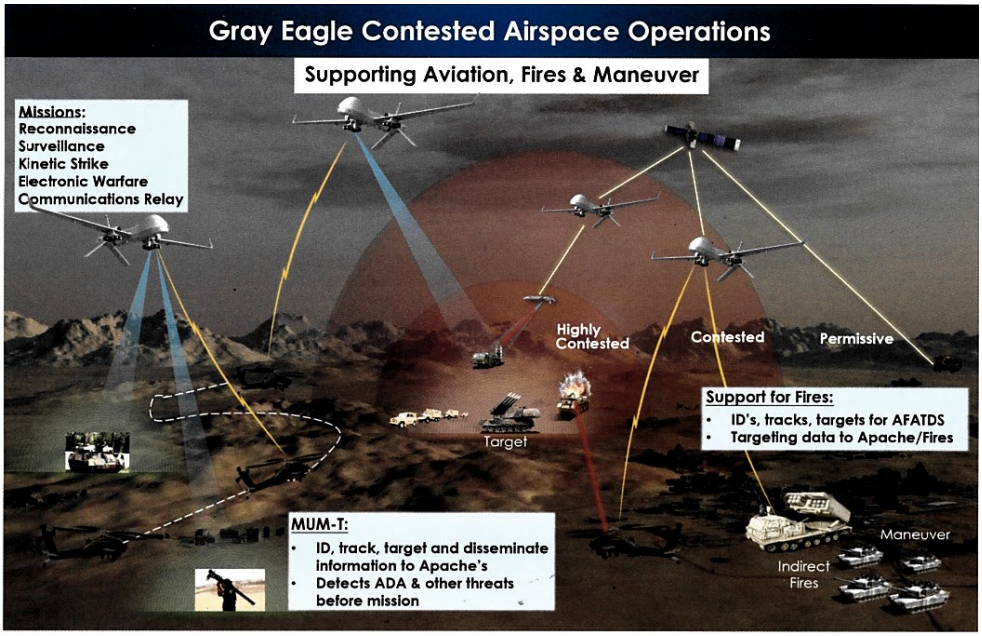

Figure 13. Gray Eagle Contested Airspace Operations. "Gray Eagle in Large Scale Combat Operations," 32.

Conclusion

Aviation is critical then, critical today, and critical tomorrow.

— Sergeant Major Woody Sullivan, "Greetings," *Army Aviation*

Army Aviation needs to integrate into a cross-functional team to be successful against the current near and peer threats in LSCO. The threat of robust A2/AD systems means Army Aviation needs to train toward the realization of limited air superiority and freedom of maneuver. Commanders and training centers need to update training to match the new Army Aviation doctrine standards set in *FM 3-04*. The Army took proactive steps by creating new doctrine to address the LSCO challenge, just as the Army did with AirLand Battle doctrine nearly half a century ago. AirLand Battle doctrine was written in the 1970s, well before being validated in

[55] Sweet, "Integration of Aviation OPS at EAB," 6; US Army Aviation Center of Excellence, *Army Aviation Equipment Modernization Strategy*, 11.

1293 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Operation Desert Storm. In addition, AirLand Battle was put to the test with exercises at JRTC, NTC, and in Operation Desert Shield. The Army may not have ten years to perfect the new doctrine before LSCO against a near or peer threat, so training environments need to be as rigorous as a complex MDO will be. JRTC and NTC have made significant advancements in training for COIN to LSCO, but both need to integrate more domains to enable cross teaming and training against the specific air defense systems of our peer threats.

To be successful against peer threats, Army Aviation needs to continue modernizing the fleet to compete with new threats in MDO. The legacy fleet, based on thirty-one year-old airframes, will only reach so far in capabilities for Army Aviation. The Army needs to keep investing more heavily in FVL's new airframes, while still balancing the upgrades for the legacy fleet to ensure the ability to fight today. The Army needs to continue developing and implementing CAB architecture software and hardware to increase prototype capabilities and expedited technology insertion. Army Aviation needs to update the AH-64 crew trainers to include cross training with UAS, to develop a seamless relationship with MUM-T. UAS operators and AH-64 crews need to train how they will fight; as a team. Army Aviation continues to improve and learn from the new doctrine in place for fighting in LSCO. Training and dissemination of lessons learned at warfighter exercises, JRTC, NTC, and past near-peer LSCO, such as Desert Storm, are key to improving and challenging future aviators who will be charged with fighting in complex MDO.

14. ABSTRACT

The Army began the testing and development of the unmanned aircraft system (UAS) capability in 1953. Since that point, the UAS has grown exponentially and proven itself as an essential capability on the battlefield in every major conflict since Desert Storm. In 2013, the United States Army Special Operations Command (USASOC) began to employ the first and only Special Operations Aviation (SOA) MQ-1C Gray Eagle UAS unit in the Army. The Army Special Operations Aviation (ARSOA) Gray Eagle unit is organized, trained, and equipped in an almost identical fashion as the conventional force (CF) Gray Eagle units. Conversely, the rotary wing units within ARSOA are organized, trained, and equipped in a very different manner than the CF rotary wing units.
The purpose of this study is to illustrate that capability gaps exist in the domains of organization, training, and equipping of the ARSOA Gray Eagle unit. A comparative analysis of ARSOA rotary wing units in relation to CF rotary wings is used to identify these capability gaps. The study then uses a modified doctrine, organization, training, materiel, leadership and education, personnel, facilities, policy (DOTMLPF-P) analysis and a capabilities-based assessment (CBA) to identify potential materiel and non-materiel solutions.

ABSTRACT

THE FIRST STEP: BUILDING A SPECIAL OPERATIONS AVIATION SPECIFIC UNMANNED AIRCRAFT SYSTEM CAPABILITY, by Joshua J. Durham, 84 pages.

The Army began the testing and development of the unmanned aircraft system (UAS) capability in 1953. Since that point, the UAS has grown exponentially and proven itself as an essential capability on the battlefield in every major conflict since Desert Storm.

In 2013, the United States Army Special Operations Command (USASOC) began to employ the first and only Special Operations Aviation (SOA) MQ-1C Gray Eagle UAS unit in the Army. The Army Special Operations Aviation (ARSOA) Gray Eagle unit is organized, trained, and equipped in an almost identical fashion as the conventional force (CF) Gray Eagle units. Conversely, the rotary wing units within ARSOA are organized, trained, and equipped in a very different manner than the CF rotary wing units.

The purpose of this study is to illustrate that capability gaps exist in the domains of organization, training, and equipping of the ARSOA Gray Eagle unit. A comparative analysis of ARSOA rotary wing units in relation to CF rotary wings is used to identify these capability gaps. The study then uses a modified doctrine, organization, training, materiel, leadership and education, personnel, facilities, policy (DOTMLPF-P) analysis and a capabilities-based assessment (CBA) to identify potential materiel and non-materiel solutions.

CHAPTER 1

INTRODUCTION

Problem Statement

In 2013, Army Special Operations Aviation (ARSOA) began to employ the MQ-1C Gray Eagle Unmanned Aircraft System (UAS), hereafter referred to as Gray Eagle, in support of special operations around the globe. Unlike the rotary wing units within ARSOA, there is not a major difference in the way that the ARSOA Gray Eagle unit is manned, trained, and equipped from that of the Conventional Force (CF) Gray Eagle units. Conversely, the rotary wing units within ARSOA have major differences in the way they are manned, trained, and equipped, in comparison to CF rotary wing units, in order to provide a unique aviation capability in support of Special Operations Aviation (SOA). Therefore, if there currently are no major differences in the way that the ARSOA Gray Eagle unit is manned, trained, and equipped, in comparison to CF Gray Eagle units, then what unique capability does the ARSOA Gray Eagle unit provide SOA? Of note, the terms manning and equipping will be used synonymously throughout this thesis with the terms organization and materiel, respectively.

Background

The concept of unmanned flight was first introduced in 1915, and by 1919 an unmanned aircraft completed a successful engagement on a captured German submarine using gyroscope-guided technology. For the Army specifically, the UAS effort began in 1953, at Fort Huachuca, Arizona, the Army's first testing and fielding location. By 1979, the Army began its first UAS acquisition program with the Aquila, which completed its operational testing in only 7 of 105 scheduled flights. This led to the Department of

1309 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Defense's first fully operational UAS program, the Pioneer, which successfully sought out SCUD missile systems and high value targets during more than 300 combat missions during Operations Desert Shield and Desert Storm. The Army continued to build its UAS capability and by the time the United States went to war in October 2001, the Army had 54 operational Hunter and Shadow unmanned aircraft in use and that number rapidly grew to over 4,000 unmanned aircraft by 2010 when the Army employed Groups 1-4 types of UAS.

Table 1. Current Systems

UAS Category	Max Gross Takeoff Weight	Normal Operating Altitude (Ft)	Airspeed	Current Army UAS in Operation
Group 1	< 20 pounds	< 1200 above ground level (AGL)	<100 Knots	RQ-11B Raven
Group 2	21-55 pounds	< 3500 AGL	<250 Knots	No current system
Group 3	< 1320 pounds	<18,000 mean sea level (MSL)		RQ-7B Shadow
Group 4	> 1320 pounds		Any Airspeed	MQ-5B, MQ-1C
Group 5		> 18,000 MSL		No current system

Source: Army UAS COE, *UAS Current Systems* (Ft. Rucker, AL. U.S. Army, 2012), 12.

The United States Army has employed the Gray Eagle for more than a decade, but it was not until 2013 that it joined the ranks of ARSOA. In 2013, Company E, 160th Special Operations Aviation Regiment (E/160) stood up as the first and only special operations aviation Gray Eagle company within the Army. Before that time Quick Reaction Capability Companies, made up of different CF UAS units, filled the SOA UAS requirements in both Iraq and Afghanistan. The formation of E/160 brought about an organic, Group 4 UAS capability to the United States Army Special Operations Command (USASOC) to support special operations forces (SOF). A holistic review of ARSOA Gray Eagle operations within SOA has not been written to capture the unique

1310 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

challenges this capability brings with it in terms of manning, training, and equipping. Currently ARSOA UAS is continuing to grow and is fielding a second Gray Eagle company (USA UAS COE 2010, 4-6). Now that the ARSOA Gray Eagle company appears to be a stable and growing capability, it is time to conduct a robust needs analysis to ensure that the unit is properly manned, trained, and equipped, from the SOF end-user perspective and not just utilizing the capabilities driven by CF requirements and analysis.

Primary Research Question

ARSOA does not employ the Gray Eagle like a CF UAS unit. However, the ARSOA Gray Eagle company is manned, trained, and equipped in almost an identical fashion as the CF UAS units. Conversely, the rotary wing ARSOA units are manned, trained, and equipped significantly different from that of rotary wing CF units. ARSOA has specific manning, training, and equipping approaches that enables its rotary wing units to have a unique capability that the CF does not have. This leads to the primary research question: are there organizational (manning), training, and materiel (equipping) capability gaps that are preventing the ARSOA Gray Eagle unit from providing a unique SOA capability? This study will illustrate whether or not the CF force development processes fully exploit the Gray Eagle's capabilities and meet SOF needs. Only by conducting a needs analysis from a SOF perspective can the force development process be reverse-engineered to ensure that ARSOA is fully exploiting the capabilities of their Gray Eagle units.

Primary Research Question

In order to answer the primary question, specific questions must be asked within the DOTMLPF-P domains of organization (manning), training, and materiel (equipping). The secondary questions to be answered in this thesis are:

1311 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

1. How does ARSOA man, train, and equip their UAS units in comparison to both CF UAS units and rotary wing ARSOA units?
2. Are there capability gaps in terms of manning, training, and equipping of the ARSOA Gray Eagle organization when compared to the rotary wing ARSOA units?
3. What are the potential materiel and non-materiel solutions to the ARSOA Gray Eagle units' domains of manning, training, and equipping, needed to provide a unique capability to SOF?

These secondary questions address specific issues under the DOTMLPF-P domains of organization, training, and materiel. Answering them will help to clearly define and focus the primary research question and this thesis.

Key Assumptions

The author makes two key assumptions in this paper. The first assumption is that the Gray Eagle and the near-term fielding of the MQ-1C Extended Range Gray Eagle UAS are the only Group 4 UAS platforms employed by ARSOA within the foreseeable future. United States Army Special Operations Aviation Command (USASOAC) has other Group 1, 2, and 3 UAS platforms, but for this study, the assumption will remain that the only Group 4 UAS employed by ARSOA is the Gray Eagle company within the 160th Special Operations Aviation Regiment (160th SOAR).

The second assumption is that the selected units used in this study represent their entire community. Specifically, this study used Company B, 3d Battalion, 82d Combat Aviation Brigade (B/3-82) to represent the CF rotary wing community; Company B, 101st Combat Aviation Brigade (B/101) to represent the CF Gray Eagle community;

1312 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Company A, 2d Battalion, 160th Special Operations Aviation Regiment (A/2-160) to represent the ARSOA rotary wing community; and Company E, 160th Special Operations Aviation Regiment (E/160) to represent the ARSOA Gray Eagle community.

Definitions and Terms

The Unmanned Aircraft System (UAS) is a complex topic, and coupled with unique aspects of the special operations community, it makes appreciation of the issues identified in this thesis challenging without an understanding of the terms presented. The key terminology in this paper will discuss; the UAS, special operations aviation, general aviation, and key terms for understanding the applied professional case study methodology.

UAS Terms

Unmanned Aircraft System (UAS): The UAS is defined as the unmanned aerial vehicle (UAV), this study will be specifically looking at the MQ-1C Gray Eagle, the ground control station (GCS), and the communications architecture (USA UAS COE 2010, 8-10). This is a key concept to understand since the UAS will commonly be referred to as a UAV, and while the UAV is a component of the overall UAS, it is not the same thing as a UAS. Unlike manned platforms, the UAS requires all the components of the system to be operational, i.e. the UAV, the GCS and the communications architecture, for the UAS to be considered operational.

Unmanned Aircraft Crewmember (UAC): UAS crewmembers will be designated in writing by their unit commander, who will specify the UAS duties and crew stations that the UACs are authorized to occupy (HQDA 2006, 13).

1313 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Unmanned Aircraft Operator (AO): The AO controls and/or monitors the actual flight of the UAS from within a GCS or similar device (HQDA 2006, 13).

Mission Payload Operator (PO): The PO is responsible for the operation of the payload sensor (HQDA 2006, 13).

Aircraft Commander (AC): The AC is responsible for control over all flight operations from pre-mission planning through debriefing. The UAS unit commander will designate aircraft commanders in writing. The AC will be responsible and have final authority for operating, servicing, and securing the UAS he or she commands, selected for each flight or series of flights, qualified and current in the UAS mission, type, design, and series (HQDA 2006, 13).

Instructor Operator (IO): The IO will train and evaluate UACs in accordance with the appropriate ATM, IOs must be designated in writing by the unit commander and be qualified and current in the UAS to be flown and must be qualified as an MC and successfully complete a Department of the Army approved IO course (HQDA 2006, 13).

Military Occupational Specialty (MOS): The grouping of duty positions requiring similar qualifications, and the performance of closely related duties (enlisted). It provides the branch, functional area, area of concentration, skill, language identification, and reporting classification used to classify the positions, and to identify individuals qualified to perform in those positions (officer) (DA PAM 611-21 2007, 12).

Additional Skill Identifier (ASI): A two-digit alpha-numeric or numeric-alpha code which identifies specialized skills that are closely related to and in addition to those required by the MOS (DA PAM 611-21 2007, 18).

Enlisted MOS 15W: Unmanned aircraft systems operator.

1314 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Remote Split Operations (RSO): Allows operators to fly UASs from stateside locations while smaller in-theater teams control takeoffs and landings. RSO has two elements: a launch and recovery element (LRE) and a mission control element (MCE). The LRE is deployed forward to launch, recover, and conduct maintenance on the UAS. The MCE remains stateside to provide command and control and provides the operators to fly the UAV while on mission.

General Aviation Terms

Pilot (PI): A rated crewmember that is qualified and current in the aircraft mission, type, design, and series (HQDA 2014c, 26).

Pilot-in-Command (PIC): A rated crewmember that is qualified, current, designated Readiness Level (RL) 1 in the aircraft mission, type, design, series, and is the individual responsible and has final authority for operating, servicing, and securing the aircraft he or she pilots (HQDA 2014c, 25).

Unit Trainer (UT): The unit commander may appoint UTs to conduct specialized training to assist in unit training programs. Rated UTs are prohibited from conducting emergency procedures training in the aircraft. UTs are also prohibited from evaluating individual, crew, and maintenance tasks (HQDA 2014c, 26).

Instructor Pilot (IP): The IP will train and evaluate aviators and other personnel in designated aircraft per the aircrew training manual (ATM). To become qualified as an IP, an aviator must be qualified as a PC and must successfully complete an approved Department of the Army instructor pilot course (HQDA 2014c, 27).

Instrument Examiner (IE): The IE will conduct instrument training and instrument flight evaluations per the ATM. To become qualified as an IE, an aviator must be an IP in

1315 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

either aircraft category, and successfully complete a Department of the Army approved course of instruction for IEs (HQDA 2014c, 27).

Readiness Levels (RLs): Aviation commanders use a series of RLs to develop individual and crew proficiencies that support collective tasks. RLs identify the training phase in which aircrew members (ACM) are participating and measure ACM readiness (HQDA 2016a, 51).

Mission Approval Process: The mission approval process for aviation operations is accomplished in three steps that must be completed prior to mission execution. The three steps are: initial mission approval, mission briefing and planning, and final mission approval authority (HQDA 2014c, 9).

Initial Mission Approval: Commanders or their designated representatives (operations officer, S–3, and so forth) determine the mission feasibility and either accept or reject the mission for the command (HQDA 2014c, 9).

Mission Briefing Officer (MBO): The MBO is the Commander or his/her designated representative that interacts with the mission crew or air mission commander to identify, assess, and mitigate risk for the specific mission. Commanders will select MBOs based on their experience, maturity, judgment, and ability to effectively mitigate risk to the aircrew and designates them by name and in writing (HQDA 2014c, 9).

Final Mission Approval Authority (FMAA/MAA): Members of the chain of command who are responsible for accepting risk and approving all aviation operations (ground and air) within their unit. They approve missions for a specific risk level. FMAAs may only approve those missions whose assessed risk level is commensurate with their command level (HQDA 2014c, 9).

1316 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Instrument Flight Rules (IFR): Instrument meteorological conditions is an aviation flight category that describes weather conditions that require pilots to fly primarily by reference to instruments, and therefore under instrument flight rules (IFR), rather than by outside visual references under visual flight rules.

Special Operations Aviation Terms

Army Special Operations Aviation (ARSOA): Designated active component forces and units organized, trained, and equipped specifically to conduct air mobility, close combat attack, and other special air operations (ADRP 3-05 2012, 47). Additionally, it is important to understand that Special Operations Aviation (SOA) supports other special operations forces units by planning and conducting special air operations in all operational environments. These specially organized, trained, and equipped aviation units provide the joint force special operations component commander with the capability to infiltrate, resupply, and exfiltrate SOF elements engaged in all special operations core activities (ADRP 3-05 2012, 47).

Battle-Rostering: Battle-rostering is defined as the designation of two or more individuals to routinely perform as a crew (HQDA 2013a, 12-13).

ARSOA Battle-Rostering: In addition to the practice of battle-rostering, individual crew members and SOA crews are further organized based on the level of mission qualification they have achieved. This modification to the aircrew model can be applied across the spectrum of SOA missions, in both training and combat, and provides the commander a clear tool to control risk while retaining mission flexibility and ensuring successful support of the ground force commander's intent (HQDA 2013a, 12-13).

1317 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Basic Mission Qualified (BMQ): BMQ pilots may perform PC or pilot (PI) duties during internal training or perform PI duties on internal/external training (HQDA 2013a, 14-15).

Fully Mission Qualified (FMQ): FMQ pilots may perform PC or PI duties during the conduct of internal and external training; they may also formally train for Flight Lead (FL) during internal training (HQDA 2013a, 14-15).

Flight Lead Qualified (FLQ/FLD): FLQ pilots may perform FL, PC, or PI duties on any internal or external training as assigned. The FLQ is primarily responsible for the planning and execution of SOA missions (HQDA 2013a, 14-15).

Applied Professional Case Study Methodology Terms

The following professional terms are part of the applied professional case study methodology. They are used by the process operators in the force development community to describe the system utilized for developing capabilities routinely and are used in the methodology of this study.

Joint Capabilities Integration and Development System (JCIDS): The JCIDS is one of DOD's three primary decision support processes for shaping the military forces to support strategic guidance documents. JCIDS is a capabilities-based approach to identify current and future capability gaps in the joint force ability to carry out joint warfighting missions and functions. The objective of JCIDS is to develop a balanced and synchronized Doctrine, Organization, Training, Materiel, Leadership and Education, Personnel, Facilities, and Policy (DOTMLPF-P) solution (F102RA 2017, 2).

Doctrine, Organization, Training, Materiel, Leadership and Education, Personnel, Facilities, and Policy (DOTMLPF-P): This is the process used to develop change

1318 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

recommendations on how to optimize the joint force's ability to operate as an integrated force. The deliberate process is characterized by the traditional route to identifying capability gaps and proposed solutions, through the use of the capabilities-based assessment process (F102RA 2017, 2).

Capabilities-Based Assessment (CBA): An analytic basis to identify capability requirements and associated capability gaps, as part of a process that produces an integrated set of DOTMLPF-P solution approaches that collectively provide the required capabilities (F102RA 2017, 3).

Functional Area Analysis (FAA): The first analytical phase of the CBA and is strictly a capabilities-based task analysis. The FAA provides the framework to assess required capabilities in the follow-on Functional Needs Assessment (FNA). The FAA is based on professional military knowledge of established doctrine and standards that are modified to account for the projected concept for future operations and organizations (F102RA 2017, 21).

Functional Needs Assessment (FNA): This is the second analytic phase in the CBA. It assesses the ability of current and programmed Army capabilities to accomplish the tasks identified in the FAA and identifies any gaps and overlaps in capabilities and the risk posed by those gaps (F102RA 2017, 22).

Functional Solutions Analysis (FSA): The FSA is the third analytic phase in the CBA. It is an operationally based assessment of potential non-materiel DOTMLPF-P and/or materiel approaches to solving or mitigating one or more of the capability needs determined from the FNA. The FSA describes the ability of each identified approach to satisfy the need. Approaches proposed by an FSA must meet three criteria: first, they

1319 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

must be strategically responsive and deliver approaches when and where they are needed; second, they must be feasible with respect to policy, sustainment, personnel limitations, and technological risk; and third, they must be attainable, in that DOD could actually resource and implement the approaches within the timeframe required (F102RA 2017, 22).

The Kotter Change Model: An eight-step process used for leading change within an organization. The model provides a foundational approach, with each stage building upon the success of the previous stage. The first four stages assist in overcoming the existing status quo and set the conditions for leading change. Stages five through seven are the action stages that move the change effort from words to action by introducing new or different practices into the organization. Without successfully completing these three action stages the effort loses momentum, the sense of urgency dissipates, and the coalition becomes marginalized. Kotter's final stage, stage eight, is reached when the changes are inculcated into the culture of the organization; the change becomes the status quo and accepted within the organization (Miller and Turner 2017, 1-3).

Modification Table of Organization and Equipment (MTOE): A table which prescribes in a single document the modification of a basic table of organization and equipment necessary to adapt it to the needs of a specific unit or type of unit (DA PAM 611-21 2007, 14).

Limitations and Delimitations

The most significant limitation of this study will be the inability to publish classified data regarding the ARSOA Gray Eagle unit of study in this thesis. The study may not clearly depict the employment of this unit without being able to annotate its

1320 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

locations around the globe and effects on the battlefield. Specifically, the study will not assess the unit's current deployed locations or operations within those areas due to classification. This is significant, as one major premise of this paper is to accurately illustrate why the ARSOA UAS unit needs to be manned, trained and equipped differently than the CF to provide a unique capability within SOA. Additionally, the study will identify capability gaps and potential materiel and non-materiel solutions to ensure the Gray Eagle provides SOA with a unique UAS capability. Specific DOTMLPF-P domains that will be addressed are the organization, training, and materiel of the unit as it is currently being employed, which will be difficult to articulate without describing the unit's current and past employment due to classification. However, this study will look at all available unclassified sources pertaining to the primary and secondary research questions.

The next limitation is that there is no research, with regards to specific literature, that addresses the employment of the ARSOA Gray Eagle unit, in relation to UAS employment by the CF. This gives no predictive notion to address going into this study. This is significant, as there is no baseline to determine whether or not changes must be made to the unit's manning, training, and equipping to ensure continued success within the special operations community. To mitigate this limitation, the methodology being used will objectively look at the aspects surrounding this gap in literature, to present a non-biased solution to the key stakeholders. The study will also illustrate that a SOF-specific needs analysis must be conducted so that ARSOA Gray Eagle units are not vulnerable to changes in the CF's force development process and to define what future changes might mean for readiness and training.

1321 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Another delimitation for this study is that it will only consider the employment of the ARSOA Gray Eagle as beginning with the creation of E/160 in 2013. The study will not include the employment of the Gray Eagle within special operations during the operations of the Quick Reaction Capability Companies, when they supported special operations forces in Iraq and Afghanistan prior to the creation of E/160.

The last delimitation is that in order to illustrate the difference between ARSOA and CF rotary wing capabilities, this study will only look at the difference between the similar ARSOA multi-mission rotary wing, MH-47, and the CF cargo rotary wing, CH-47 units. This comparison will be used to identify any gaps in the manning, training, and equipping of ARSOA Gray Eagle and the CF Gray Eagle units, in comparison to ARSOA and CF rotary wing units. This delimitation will not take away from the credibility of this study as the only other similar units between ARSOA and the CF would be between the ARSOA multi-mission rotary wing, MH-60, and the CF utility rotary wing, UH-60 units.

Significance of Study

The results of this study will identify any capability gaps in the manning, training, and equipping of the ARSOA Gray Eagle unit that may prevent it from providing a unique UAS SOA capability. This will be based on a comparative analysis of the CF Gray Eagle unit, by comparing the similarities and differences between the ARSOA and CF Gray Eagle units. The study will then look to the ARSOA rotary wing units for potential materiel and non-materiel solutions by analyzing the differences in the ARSOA rotary wing units from those of the CF rotary wing units. This is significant because it will not only identify the domains in which capability gaps exist, but will also look to an established SOA unit for potential solutions.

1322 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

R1: Initial Personal Recommendation

The applied professional case study is a research methodology that incorporates three different assessments throughout the process, R1, R2, and R3. The initial assessment, or R1, is the author's perspective, bias, and assumptions prior to beginning the review of literature. This initial assessment provides a starting point to the research and gives it credibility throughout the rest of the process.

The first part of the R1 discusses the primary research question and why it is important to the author and the key stakeholders within USASOC. The primary research question in this study is: are there organizational, training, and materiel capability gaps that are preventing the ARSOA Gray Eagle unit from providing a unique SOA capability? The author developed this research question after spending approximately 18 months in the only ARSOA Gray Eagle company, E/160, as the executive officer just prior to beginning this study. In addition to those 18 months in E/160, the author spent over 5 years in the 160th SOAR, primarily within the rotary wing units. This experience gave the author an understanding of the Gray Eagle, its role within the 160th SOAR, and the Soldiers who operate and maintain the Gray Eagle. With that understanding, the author believes there are capability gaps that must be addressed for this platform to perform at the same level as the rotary wing units within the 160th SOAR. The author has a vested interest in this study because he will be returning to the 160th SOAR after this study to work with E/160 and believes that it must begin to mirror the ARSOA rotary wing units in terms of manning, training, and equipping, to provide a unique SOA UAS capability to the special operations community.

This study is important because if E/160 is expected to provide the same unique capabilities as the rotary wing units within the 160th SOAR, then the key stakeholders

1323 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

need to look at the capability gaps that E/160 has in terms of manning, training, and equipping when compared to the rotary wing units in the 160th SOAR. The Gray Eagle is still within its first five years of employment within ARSOA, and the earlier that these capability gaps can be identified and addressed, the easier it will be to define the unique UAS capability that E/160 brings to the special operations community. Additionally, a second Gray Eagle company is currently being fielded with an August 2018 activation date. Any changes to the organization, training, and materiel of this new company will be less intrusive if identified and implemented early during the standing up of this new company.

The second part of the R1 addresses why this study is important and the possible consequences if this topic is not addressed. The demand for combat air patrols provided by ARSOA Gray Eagle is going to increase, as evidenced by the fielding of a second Gray Eagle company within the 160th SOAR. Additionally, the Department of Defense (DOD) is continuing to invest in the advancement of the Gray Eagle with the production of the Extended Range (ER) Gray Eagle, which is scheduled to undergo initial operational testing and evaluation (IOT&E) by ARSOA in fiscal year 2018 (FY18). The United States Special Operations Command (USSOCOM) is investing in the advancement of a unique SOA UAS capability and identifying the capability gaps in terms of organization, training, and materiel will ensure that these investments are made to the most critical capability gaps identified in this study. If this analysis is not done and investment is made in areas that do not truly increase the capability provided, the consequence will be that USSOCOM used constrained fiscal resources without equitable payoff.

1324 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The final portion of the R1 identifies the potential for a solution to the problem statement, the methodology by which it could be answered, and the author's initial recommended solutions. The author believes that there are potential solutions to the problem statement and that looking to the ARSOA rotary wing units for these solutions should be the starting point. The 160th SOAR has had 36 years to develop and implement unique SOA capabilities. This is in line with the SOF truth that special operations capabilities cannot be mass produced. E/160 is reaching its 5th year of conducting operations as part of the 160th SOAR and the unit needs to start establishing unique SOA UAS capabilities to support special operations with abilities not offered by CF UAS units. Informing key stakeholders of these potential solutions, with a rich description of the environment, will persuade them to make key changes that will ensure this capability is poised to support the unique requirements of special operations.

This problem will require the methodology to use the correct data to determine possible solutions. To determine the potential capability gaps in E/160's manning, training, and equipping, this study will need to look at data that accurately depicts E/160's current organization structure, training process, and equipping. Additionally, this study will look at this same data from ARSOA rotary wing units, CF rotary wing units, and CF Gray Eagle units. After gathering the right data, an applied professional case study will be used,

> Case studies are a useful method for conducting qualitative research for problem areas that are human-centric, dynamic, volatile, and contain a mix of stakeholders, interests, variables and information concepts that demand a deep understanding of context in order to produce informed policy choices" (Creswell, 2009, 2013, 2014; Yin, 2014).

The study will then use a comparative analysis from the data gathered through the case study and use a modified DOTMLPF-P Capabilities Based Assessment (CBA) to

1325 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

determine the results. A CBA is appropriate since it is a structured three phased process that identifies and documents capability gaps; determines the attributes of a capability or combination of capabilities that would resolve the gaps; and identifies non-materiel as well as materiel approaches for possible solutions. By conducting the applied professional case study and then analyzing it using the CBA, we get the functional solution analysis (FSA). This will identify a resolution, and will look to potential DOTMLPF-P approaches, recommendations, and solutions to mitigate or eliminate the capability gaps and will produce suggestions to implement ideas for non-materiel DOTMLPF-P approaches; and ideas for materiel approaches.

Conclusion

Since its inception in 2013, the ARSOA Gray Eagle unit has enabled special operations across the globe with phenomenal results. This success brought an increased demand within ARSOA which led to the current fielding of another MQ-1C Gray Eagle company within ARSOA. This chapter discussed the background, the problem, and the process by which this study will be conducted. The next chapter will analyze the literature used for this study.

1326 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CHAPTER 2

LITERATURE REVIEW

Introduction

The purpose of this research is to gain a rich understanding of the unique capabilities required by the ARSOA Gray Eagle unit to meet special operations specific requirements, and to persuade the Chief Decision Maker (CDM) and key stakeholders to affect change. The literature is primarily from the Department of Defense (DOD) and other federal agencies because the purpose of this study is to persuade key stakeholders within the DOD. By primarily using the professional body of knowledge, it tailors the information and makes it credible to the target audience. This remains in line with the research methodology as a professional applied case study.

The specific areas that will be addressed in this chapter are the manning, training, and equipping of the unit and whether it is specifically designed to support special operations in the same manner as the rotary wing ARSOA units.

Key Literature

The following graph depicts the literature reviewed in this study and how each piece of literature specifically applies to the different aspects of this paper.

The *United States Army Roadmap for UAS 2010-2035* is the Army's vision to develop, organize, employ, and build a comprehensive strategy for defining future UAS requirements. This publication breaks down this strategy into the time periods of near (2010-2015), mid (2016-2025), and far (2026-2035). Through these different time frames, the document focuses on issues such as identifying current gaps in capabilities, integrating UAS into other Army operations such as networking and cargo capabilities, and increasing the overall capability of the UAS while reducing its size, power, and weight requirements. This roadmap is reviewed every two years, but a new edition has

1328 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

not been published since this initial document. While the document is over seven years out of date, it still provides a good assessment as to whether or not the Army is on the right track to meet its intended goals.

This reference applies to this study as it addresses both the primary and secondary research questions of this thesis. Specifically, it describes the UAS in terms of manning, training, and equipping, and it breaks down the assessment into the DOTMLPF-P domains, which falls directly in line with the methodology used in this study. Additionally, this document discusses the challenges with UAS operations within the NAS and addresses many other issues with the employment of the UAS, which may fall outside the scope of this study, but are still necessary to consider.

The *Unmanned Systems Integrated Roadmap FY2013-2038* is a document intended to "articulate a vision and strategy for the continued development, production, test, training, operation, and sustainment of unmanned systems technology across DoD." It looks at both current and future capabilities in a 25-year window to address where UAS is now, and to develop a strategy to determine where it should go. While this document does not specifically address special operations, it does identify with many of the same gaps in capabilities that could be used within special operations as well as with CFs. Additionally, it addresses the manning, training, and equipping aspects of this thesis.

Much like the *United States Army Roadmap for UAS 2010-2035*, this document discusses UAS operations in terms of near, mid, and far time frames. Unlike the *United States Army Roadmap for UAS 2010-2035*, this publication is not solely focused on the Army UAS program but on the Department of Defense as a whole, which gives this document a more strategic aim. Specifically, the *Unmanned Systems Integrated Roadmap*

1329 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

FY 2013-2038 discusses strategic planning and policy, combatant commander mission and capability needs, technologies for unmanned systems, operating environment, sustainment and logistics, training, and international cooperation.

Of the topics discussed in this thesis, *The Unmanned Systems Integrated Roadmap FY 2013-2038* addresses the equipping aspect in the most detail. For example, it addresses several types of munitions that could improve the capabilities of the MQ-1C Gray Eagle aerial vehicle. One of which is the Direct Attack Guided Rocket (DAGR). The DAGR is a 2.75-inch laser guided rocket that is fully compatible with the current Hellfire system. This new munition would potentially allow the MQ-1C Gray Eagle to carry up to four times as much payload as its current configuration. Additionally, this document extensively describes the communications architecture and potential use of existing networks, specifically the Defense Information Systems Network (DISN) and the teleport standard tactical entry point (STEP) sites. The ability to plug into these global networks and gain access to satellite coverage around the globe would provide an increased capability for ARSOA UAS in terms of its operational reach. *The Unmanned Systems Integrated Roadmap FY 2013-2038* provides a great deal of information from very specific aircraft-defining characteristics to broad strategic level policy. It provides insight to many of the topics discussed in this thesis and other aspects within the UAS community.

The *MQ-1C Gray Eagle Selected Acquisition Report (SAR),* as of the FY2017 President's budget, discusses several topics relevant to this study. First, it discusses the proposed employment design of Gray Eagle units in terms of organization. Specifically, it addresses how the unit is intended to operate and why it is organized the way that it is. In

1330 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

support of United States Army Divisions, the UAS company is part of the combat aviation brigade (CAB); in support of Intelligence Command (INSCOM), it is part of the 116th Military Intelligence Brigade, and in support of USASOC it is part of the 160th SOAR. Within each of these organizations, the UAS company is broken down into three identical platoons, giving the commander extreme flexibility to employ this asset. This document explains that the intent of the UAS company's structure from inception was for each platoon to be able to operate independently at three geographically dispersed locations.

The Chairman of the Joint Chiefs of Staff Instruction (CJCSI) 3255.01- Joint Unmanned Aircraft System Minimum Training Standards document provides the basis for joint unmanned aircraft system minimum training standards and identifies the training requirements for UAS crewmembers to operate in support of a joint force commander. It breaks the requirements down into three categories: Basic UAS Qualification (possessing the general aviation and UAS knowledge to safely operate a UAS), possessing the skills required to both operate the UAS and maintain situational awareness to execute tasks, and Joint Mission Qualification (understanding the UAS mission/objective and its role in accomplishing the larger military operation). This document directly applies to this thesis as it is essentially a contract between the Department of Defense and the FAA, establishing the minimum training requirements that a UAS operator must possess to operate in the NAS.

The *TC 3-04.63 MQ–1C Unmanned Aircraft System Commander's Aircrew Training Program and Aircrew Training Manual* applies to Gray Eagle crewmembers and their commanders. The purpose of this document is to standardize aircrew training

1331 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

programs and flight evaluation procedures by providing specific guidelines for executing UAS aircrew training. This training circular outlines both the individual and collective training requirements for crewmembers in order to advise the commander on an effective aircrew training program that supports combined arms training. Of note, the *MQ–1C Unmanned Aircraft System Commander's Aircrew Training Program and Aircrew Training Manual* is combined into one document to cover both the Gray Eagle specific aircrew training program and the commander's aircrew training program for individual, crew, and collective training. While the Commander's Aviation Training and Standardization Program incorporates the UAS, it admittedly states that the UAS integration is still developing and needs refinement, which makes the *MQ–1C Unmanned Aircraft System Commander's Aircrew Training Program and Aircrew Training Manual* publication the most relevant document to Gray Eagle operations. This is significant because this study will examine the corresponding CF and ARSOA rotary wing publications as part of the analysis for this thesis. For those elements, there are two distinct publications, an airframe specific aircrew training manual and a general aviation commander's aircrew training program for individual, crew, and collective training. Additionally, it is important to note that the CF and ARSOA Gray Eagle units both use this same document.

The aircrew training program outlined in this publication applies to crewmembers that perform duties controlling the flight of a UAV or the operation of its mission equipment. This includes starting the engine, takeoff and/or landing the UAV and consists of qualification, refresher, mission, and continuation training. It outlines the requirements for qualification in the Gray Eagle, criteria for readiness level progression,

1332 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

flight activity category designation, flight hour/currency requirements and annual task and iteration requirements. This publication also outlines the testing and evaluating requirements for crewmembers during a proficiency flight evaluation, annual proficiency and readiness evaluation, and other crewmember proficiency based testing.

In summary, this document contains the necessary guidance for a Gray Eagle company commander to execute the aircrew training program that covers everything from individual to collective unit training. Additionally, this document is the aircrew training manual for the Gray Eagle and is the basis for the crewmember's training from the individual to collective training levels.

The *TC 3-04.11 Commander's Aviation Training and Standardization Program* is the commander's guidance for implementing a standardized aviation training program. It applies to all individuals flying Army aircraft and for the purposes of this study, it directly applies to CH-47F and Gray Eagle crewmembers. It does not apply to ARSOA MH-47G crewmembers, as ARSOA has its own publication for the execution of the commander's aircrew training program.

This publication focuses on the implementation of an effective, standardized aircrew training program that supports the mission of the combat aviation brigade. It outlines the individual responsibilities in executing the training program from the brigade commander down to the individual crewmember. Like the aircrew training manuals, it addresses individual qualification, currency, and flight hour requirements, but these are not the focus. In contrast to an aircrew training manual, the focus of this document is to serve as a guideline to all Army aircraft as a holistic approach to Army aviation training and standardization. For example, it specifically addresses aircrew training plan

1333 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

management, doctrinal training concepts, unit collective training requirements, and the implementation of the Army standardization program.

The *ARSOA TC 3-04.11 Commander's Aircrew Training Program for Individual, Crew, and Collective Training* is the keystone publication that establishes the requirements for commanders at all levels to develop, manage, and administer a comprehensive aircrew training program. In the context of this study, this publication applies directly to the ARSOA MH-47G crewmembers, but does not address ARSOA Gray Eagle crewmembers.

This reference covers much of the same material as the *TC 3-04.11 Commander's Aviation Training and Standardization Program*, but applies only to ARSOA crewmembers. This publication addresses the responsibilities of the 160th SOAR Commander down to the individual crewmember, aircrew training program administration, risk management, training and evaluation requirements, and standardization for aviation records. The most important element of this publication, with regards to this study, is that it addresses how ARSOA battle rosters their crews in terms of PI, PC, BMQ, FMQ, and FLD designations. This is an important distinction as the *TC 3-04.11 Commander's Aviation Training and Standardization Program* also addresses crew battle rostering but only in terms of PI/AO and PC/AC designations. This distinction will be addressed in chapter four, but it is important to note that while the ARSOA MH-47G crewmembers have additional crewmember designations of BMQ, FMQ, and FLD, the ARSOA Gray Eagle crewmembers only have the designations of AO and AC. *The ARSOA TC 3-04.11 Commander's Aircrew Training Program for Individual Crew, and Collective Training* specifies the type of crew mix (PI, PC, BMQ, FMQ, FLD)

1334 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

required for different mission sets (internal training, external training, administrative support, and tactical).

The *TC 3-04.34 Aircrew Training Manual, Cargo Rotary wing, CH-47D/F* applies to all CH-47 crewmembers and their commanders in the active Army, the Army National Guard Bureau/United States Army National Guard, the United States Army Reserve, and provides specific guidelines for executing CH-47D/F aircrew training. This publication is the basis for crewmember qualification training, refresher training, mission training, and continuation training and evaluation requirements.

This reference is used in conjunction with the *TC 3-04.11 Commander's Aviation Training and Standardization Program* publication to help commanders and crewmembers execute the aviation training program. The main difference is that the *TC 3-04.34 Aircrew Training Manual, Cargo Rotary wing, CH-47D/F*, provides the performance standards and evaluation guidelines for every individual/mission/collective task, so that crewmembers know the level of performance expected. It is the primary tool used by commanders and standardization officers to implement the aircrew training program. This manual is intended to support the unit's mission essential task list by enhancing training in individual and aircrew proficiency.

The *ARSOA Aircrew Training Program Aircrew Training Manual Multi-Mission Rotary wing MH-47*, much like the *TC 3-04.34 Aircrew Training Manual, Cargo Rotary wing, CH-47D/F*, is the basis for crewmember qualification training, refresher training, mission training, and continuation training and evaluation requirements. It applies to all MH-47 crewmembers, their commanders, and standardization officers. It is used in conjunction with the *ARSOA TC 3-04.11 Commander's Aircrew Training Program for*

1335 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Individual Crew, and Collective Training and other applicable publications to aid both the individual and commander in developing an effective and standardized aircrew training program for the unit. It establishes the task, conditions, and standards for all individual and collective tasks for employment of the MH-47 aircraft. Specific to this study, the *ARSOA TC 3-04.11 Commander's Aircrew Training Program for Individual Crew, and Collective Training* outlines specific special operations aviation tasks that are not listed in the CF *TC 3-04.34 Aircrew Training Manual, Cargo Rotary wing, CH-47D/F*. These tasks provide additional capabilities to the special operations community that the CF cargo rotary wing, CH-47D/F, units cannot provide.

After reviewing the applicable aircrew training documents for the ARSOA and CF units used in this study, the following discussion on aircrew training progression and crewmember designations is necessary to understand the results of this study described in chapter four. This discussion will begin with describing the aircrew training program, which is almost identical for manned and unmanned airframes, and will conclude with aircrew member designations that distinguish the ARSOA process from the CF process, and is a key point to understand for this study.

Readiness levels (RLs) are used by aviation commanders to determine the proficiency of crewmembers in their base, mission, and additional tasks. RLs are designated progression points that range from RL1 to RL3, with RL3 being the designation for a crewmember focusing on base tasks, to a mission ready crewmember with an RL1 designation (HQDA 2016a, 51). Base tasks, or 1000 series tasks, are made up of individual tasks or maneuvers that a crewmember is expected to be able to perform, both in and out of the airframe. An example of a base task for a CH-47F rated

1336 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

crewmember would be to perform hovering flight, task #1038 (HQDA 2013b, 101). Once the crewmember demonstrates proficiency in all base tasks listed in that airframes applicable aircrew training manual, they are designated RL2. During RL2 training, the crewmember must demonstrate proficiency in all mission and additional tasks (or 2000 series and 3000 series tasks, respectively) that support the unit's mission essential task list, as assigned by that crewmember's aircrew training program commander. An example of a mission task for a Gray Eagle operator would be to operate synthetic aperture radar, task #2305 (HQDA 2014b, 200). Once a crewmember completes all RL2 training requirements, they are designated RL1.

Once a crewmember is designated RL1, they continue their flight training through continuation training which has different requirements based on that crewmembers Flight Activity Category (FAC). FAC levels are designated by the brigade level commander and are based on flight task requirements and the proficiency required by the individual crewmember's MTOE or TDA position. FAC levels are broken down into FAC 1 through FAC 3. A FAC 1 position requires a high degree of proficiency in the tactical employment of the assigned airframe. A FAC 2 position requires the same proficiency in individual and crew tasks as a FAC 1 position but does not necessarily require the same collective proficiency in unit tasks. FAC 3 positions are not authorized to perform crewmember duties in their assigned airframes but must complete applicable simulator hour requirements, if a compatible simulator is available. Each FAC level has a corresponding semi-annual flight hour requirement, that is considered the continuation training as previously discussed (HQDA 2016a, 66-67). For example, an RL1, FAC 1, MH-47G rated crewmember has a semi-annual flight hour requirement of 60 hours, 30 of

1337 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

which must be completed using night vision goggles. An RL1, FAC 2, MH-47G rated crewmember has a semi-annual flight hour requirement of 33 hours, 18 of which must be completed using night vision goggles (HQDA 2013a, 47; ATM 2014, 19). In addition to semi-annual flight hour requirements, crewmembers have an annual requirement to complete an annual proficiency and readiness test (APART). The APART is conducted each year during a crewmember's APART window which is based on their birth month. The APART is slightly different for each airframe, but it essentially consists of a hands-on evaluation, a written evaluation, and a flight physical (DD Form 2992, Medical Recommendation for Flying Duty) (HQDA 2016a, 71).

Crewmembers have an obligation to complete applicable RL progression and continuation training but are also required to progress in their crewmember designation. In the Gray Eagle community, UAS crewmembers (UACs) have the following designations; unmanned aircraft operator (AO), mission payload operator, (PO), aircraft commander (AC), unit trainer (UT), instructor operator (IO), standardization instructor operator (SO), and mission commander (MC). Upon successful completion of a Department of the Army approved Gray Eagle qualification course and designation in writing from the aircrew training program commander, UACs begin their aviation careers with the designation as an AO, and a PO.

An AO is responsible to control the flight of an UAS or the operation of its mission equipment and remain tactically and technically proficient as an UAC. The individual operator should have the ultimate goal of achieving AC status (HQDA 2016a, 51). An AC has the same requirements as an AO, but additionally they are responsible for the overall safety of the UAV, be proficient in the UAV and all aspects of the unit

1338 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

mission essential task list, the conduct of all operational and training aspects of a specific mission, all actions of the crew, assigning duties to the crew, and for accomplishing the assigned missions.

From there, the UAC looks to progress to a UT, who has all the responsibilities of an AC but is additionally responsible to instruct in appropriate tasks and subjects, recognize errors in performance or understanding, make recommendations for improvement, train to standards, and document training (HQDA 2014b, 24-32). After designation as a UT, and with input and concurrence of the command level leadership, a UT will attend an approved Department of the Army Gray Eagle Instructor Operator (IO) course to undergo training. Of note, a UAC does not have to be designated as a UT to be sent to the IO course, this just represents a normal progression for a UAC from initial assignment to designation as an IO.

After successful completion of the IO course and designation in writing from the aircrew training program commander, that UAC is designated as an IO. The IO has all the requirements of a UT and is the unit's primary trainer and evaluator of all UACs. The SO is the final aircrew designation for a UAC. Normally, an IO will train for multiple years before being recommended by the command to be designated as an SO. After designation in writing by an aircrew training program commander, an IO is authorized to perform SO duties. An SO has all the responsibilities of an IO and primarily trains and evaluates the unit's IO. Additionally, an SO is the primary advisor to the commander on all aspects of the unit's aircrew training program (HQDA 2006, 14).

The CH-47F and MH-47G rated aviators used in this study have the following aircrew designations; Pilot (PI), Pilot in Command (PC), Unit Trainer (UT), Instructor

1339 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Pilot (IP), Instrument Examiner or Instrument Flight Examiner (IE or IFE), and Standardization Instructor Pilot (SP). Of note, rated aviators have other aircrew designations, but those are not applicable for the purposes of this study (HQDA 2014c, 27).

Upon successful completion of a Department of an Army approved qualification course, and designation in writing by the ATP commander, new rated aviators begin their aviation career with the designation as a PI. A PI has the responsibility to remain tactically and technically proficient in all aircrew member tasks as dictated by the applicable aircraft training manual. PIs should take advantage of every training opportunity with the goal of attaining designation as a PC.

After demonstrating proficiency in all required aircraft tasks, successfully completing a PC evaluation in accordance with applicable publications, displaying proper judgement and maturity, and being designated in writing by the ATP commander, a rated aviator is then designated as a PC. A PC has all the responsibilities as a PI, but is additionally responsible to ensure the overall safe and effective operation of the aircraft, to serve as the unit's first-level trainer, be proficient in the aircraft and all aspects of the unit's collective tasks. The PC is responsible for the safety of all occupants, and the conduct of all operational and training aspects of a specific mission, responsible for all actions of the crew, responsible for assigning duties to the crew, and responsible for accomplishing assigned missions (HQDA 2014c, 26).

At this point in the aircrew progression process, it is important to note several significant differences between rotary wing pilots and UAS operators. First, the Army's rotary wing pilots are primarily warrant officers and the Army's UAS operators are

1340 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

primarily enlisted soldiers and non-commissioned officers. To be clear, there are also commissioned officers that are rated aviators and there are warrant officers that are UAS operators, but for the purposes of this study, they are not included in the discussion. The next significant difference is that warrant officers track different career paths during their professional careers. Unlike UAS operators, a warrant officer's progression to IP is dependent upon the career path they decide to track. For example, a warrant officer may decide that they would like to track safety to become an aviation safety officer and because of that, they would never achieve an aircrew designation as an IP. There are a few warrant officers that track multiple career paths, but it is not the norm. In contrast, UAS operators do not have multiple career track options like warrant officers and because of this each UAS operator should strive to progress to IO.

For comparison in this study, a warrant officer who decides to career track IP would look to progress to the designation of a UT after achieving PC status. A UT has the same responsibilities as a PC; but in addition, a UT has demonstrated the ability to train other pilots and focuses primarily on RL 2 and RL 1 progression training. At some point in the warrant officer's career and service as a UT, they will attend a Department of the Army instructor pilot qualification course resulting in designation as a unit IP by the ATP commander. IPs have the same responsibilities as a PC, but in addition, they serve as the primary instructors and evaluators for the unit. Normally after a few years as an IP, the command will determine whether or not to give an IP an SP evaluation based on their performance as an IP. After successfully completing an SP evaluation in accordance with applicable publications and a designation in writing by the ATP commander, an IP is designated as an SP. An SP has all the responsibilities of an IP but SPs are also primarily

1341 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

responsible for the training and evaluation of IPs, and serve as the primary advisor to the commander on all matters pertaining to the unit's ATP.

The final aircrew designation for this study is the designation as an IE or IFE. There is not a correlating designation within the UAS community but it is still relevant for the purpose of this study. The reason is that the Gray Eagle is not rated for IFR flight, and because of that, there is no need to designate UACs as IEs. To be designated as an IE, an aircrew member must already be designated as an IP and successfully complete a Department of the Army approved IE qualification course and be designated in writing by the ATP commander. An IE has the primary responsibility to administer instrument flight evaluations within the unit. The designation as an IE is not airframe specific like the other aircrew designations; for example, an IE whose primary aircraft is a CH-47 can give an instrument evaluation to an aviator whose primary aircraft is a UH-60 (HQDA 2014c, 27).

An understanding of the aircrew member training, progression, and aircrew designation processes of both the manned and unmanned platforms discussed in this study is essential to gain an understanding of the unique ARSOA mission qualification and battle-rostering process discussed in the next section.

ARSOA rotary wing units use a unique battle-rostering process that is based on mission qualification. This process is unique to ARSOA and is not used by CFs rotary wing units, B/101, or by E/160, that is key to note for the purposes of this study. The intent of this unique battle-rostering process is to ensure successful accomplishment with the minimum amount of risk to the force and to the SOA mission. ARSOA has the following mission qualification designations; basic mission qualified (BMQ), fully

1342 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

mission qualified (FMQ), and flight lead qualified (FLD). Once a rated crewmember successfully completes the special operations basic mission qualification course conducted by the 160th Special Operations Aviation Training Battalion, that crewmember is designated as an RL 1, PI, BMQ, and assigned to an operational company within the 160th SOAR. The rated crewmember then conducts mission training with the goal of achieving FMQ designation. After extensive training and successful completion of an FMQ evaluation and designation in writing by the ATP commander, that crewmember is designated as an FMQ. The final mission qualification is that of FLD. Significant to this study, the FLD qualification usually takes many years to achieve, and is a designation that not every rated crewmember in the 160th SOAR will achieve. It illustrates mastery of all SOA required mission sets and the highest degree of tactical and technical proficiency. After many years of extensive training, successful completion of a FLD evaluation, and designation in writing by the 160th SOAR Commander, that crewmember is designated as a FLD. These mission qualifications are used to determine the right battle-rostering based on mission requirements.

The *Technical Manual Operator's Manual for the MH-47G, TM 1-1520-272-10-1* provides complete operating instructions and procedures for the multi-mission rotary wing, MH-47G. Specifically, it covers aircraft and systems description and operation, avionics, mission equipment, operating limits and restrictions, weight/balance and loading, performance data, normal procedures, and emergency procedures for the MH-47G.

The *Operator's Manual for the CH-47F, TM 1-1520-271-10-1* provides complete operating instructions and procedures for the cargo rotary wing, CH-47F. Specifically, it

1343 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

covers aircraft and systems description and operation, avionics, mission equipment, operating limits and restrictions, weight/balance and loading, performance data, normal procedures, and emergency procedures for the CH-47F.

The *Operator's Manual for the MQ-1C Unmanned Aircraft System, TM DTM 1-1550-697-10-1*, provides complete operating instructions and procedures for the unmanned aircraft system, MQ-1C. Specifically, it covers aircraft and systems description and operation, avionics, mission equipment, operating limits and restrictions, weight/balance and loading, performance data, normal procedures, and emergency procedures for the MQ-1C.

The *Unmanned Aircraft System Flight Regulations, AR 95-23*, much like the *TC 3-04.11 Commander's Aviation Training and Standardization Program*, provides guidance on UAS crewmember training, risk management, currency requirements, training and standardization. In addition, this regulation also covers flight rules, UAS general provisions, and management of UAS resources. It is not specific to the Gray Eagle, but applies to all categories of UAS employed by the United States Army active duty/reserve/national guard units and supporting civilian contractors.

Flight Regulations, AR 95-1, covers the same topics and is applicable to the same organizations as the *Unmanned Aircraft System Flight Regulations, AR 95-23*, but while it is applicable to UAS, it is not specific to UAS and does not address UAS specific policy. The only UAS specific guidance in this publication is guidance that addresses the recovery operations associated with unmanned aircraft. For the purposes of this study, *Flight Regulations, AR 95-1*, applies directly to the CH-47 and MH-47 units used for this thesis.

1344 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The United States Army Force Management Support Agency (USAFMSA) provides online access to the *Force Management System* website that provides extensive information on how Army units are manned and equipped. For this study, the website was used to access the Modification Table of Organization and Equipment (MTOE) for the Army units used in this study: Company B, 3d Battalion, 82d Combat Aviation Brigade (CF CH-47F unit); Company A, 2d Battalion, 160th Special Operations Aviation Regiment (ARSOA MH-47G unit); Company B, 101st Aviation Regiment (CF MQ-1C unit); and Company E, 160th Special Operations Aviation Regiment (ARSOA MQ-1C unit).

An MTOE is an authorization document that prescribes the modification of a basic Table of Organization and Equipment (TOE). It is a document that prescribes the wartime mission, capabilities, organizational structure, and mission essential personnel and equipment requirements for military units, and adjusts it as necessary to adapt it to the needs of a specific unit or type of unit. For example, the MTOE for an MQ-1C Gray Eagle company shows how many personnel, by grade, and how many airframes, by type, would be required for a company to conduct its wartime mission. For the purposes of this thesis, the different MTOE documents for each of the units being analyzed in this study clearly depicts the differences and similarities between the CF and ARSOA units.

The documents *USASOC Strategy 2035* and *ARSOF 2022* provide guidance for the development of future ARSOF operational and institutional capabilities. For the purposes of this study, these two documents were used to form the basis by which the Chief Decision Maker (CDM) for this study would evaluate the proposed results of this thesis, through the R3: Stakeholder Recommended Solution.

1345 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Conclusion

The review of the cited literature primarily from the military's professional body of knowledge offers insight into the primary and secondary research questions, and also establishes the foundation for the remainder of this thesis. Additionally, this review of literature was conducted in line with the research methodology, using sources from the professional body of knowledge, applicable to the CDM. The next chapter, Chapter 3, will outline the research methodology for this study.

1346 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CHAPTER 3

RESEARCH METHODOLOGY

Purpose of the Research and the Research Questions

The purpose of this study is to persuade the Chief Decision Maker (CDM), the commander of USASOC, that the proposed solutions to E/160's manning, training, and equipping capability gaps, would enable E/160 to provide a unique UAS capability to special operations. The main concerns of the CDM are to obtain next generation unmanned aircraft systems that provide longer operational range and over horizon observation; can be launched and recovered by tactical units; and employ advanced unmanned aircraft systems and intelligence collection capabilities at the tactical level. This includes the concern to provide joint force commanders with professionals who are agile, adaptive, flexible, bold, innovative, and possess a high degree of advanced training; provide the nation with premier special operations forces; and deliver appropriate and effective capabilities to joint force commanders and interagency leaders across the entire spectrum of conflict under any operating conditions. The CDM must broaden the range of special operations aviation-related individual training and education including unmanned aerial systems; and improve army unmanned aerial-system programs of record (Raven, Shadow and Gray Eagle) to meet joint expeditionary tactics, techniques, procedures, forward-based networking and sensor requirements (HQDA 2014a, 24; ARSOF 2035 2017, 3-6).

In order to implement the findings from this research, the CDM would have to utilize the Army Joint Capabilities Integration Development System (JCIDS), the Defense Acquisition System (DAS), and the Planning, Programming, Budgeting, and

1347 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

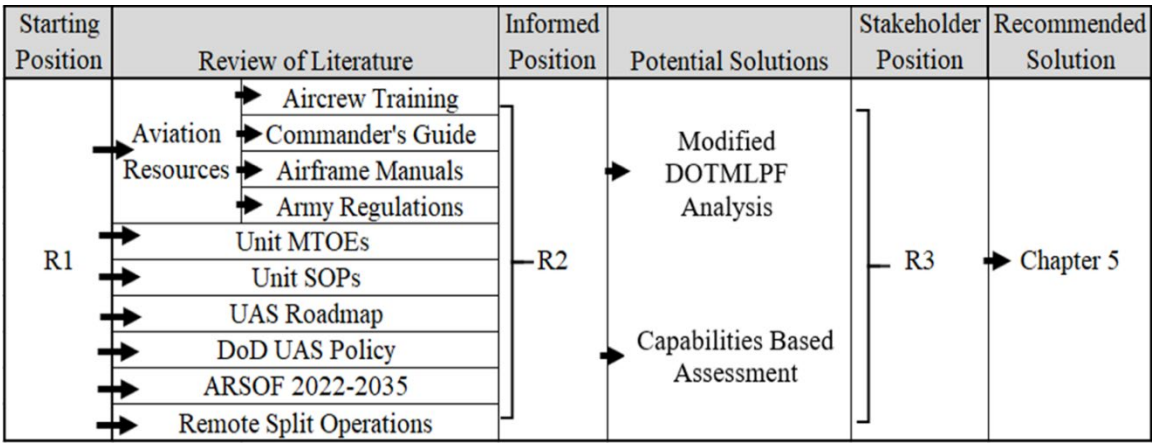
Execution (PPBE) process to develop new solutions to the organization, training, and equipping of USASOC Gray Eagle units (F102Ra 2017, 2). The USASOAC Commander, the 160th SOAR Regimental Commander and the 160th SOAR Battalion Commanders are the other stakeholders who will be influenced by the changes to the units' organization, training, and equipping and who will also be the ones to implement these changes. Additionally, the research findings would have to be in line with current national strategic guidance to include the National Security Strategy (NSS), the National Defense Strategy (NDS), and the National Military Strategy (NMS). The CDM's primary evaluation criteria to assess the results of this research will be based on these available resources: the NSS, the NDS, and the NMS.

In order to answer the primary research question, three secondary questions were developed: (1) How does ARSOA man, train, and equip their UAS units in comparison to both CFs UAS units, and rotary wing ARSOA units? (2) Are there capability gaps in terms of manning, training, and equipping of the ARSOA Gray Eagle organization when compared to the rotary wing ARSOA units? (3) What are the potential materiel and non-materiel solutions to the ARSOA Gray Eagle units' domains of manning, training, and equipping, needed to provide a unique capability to SOF?

To answer these questions, the author conducted a comparative analysis of the literature within the professional body of knowledge dealing with the organization, training, and equipping of ARSOA UAS and rotary wing units, and CF UAS and rotary wing units. The professional body of knowledge primarily included training manuals, technical manuals, Army and Joint Publications, MTOE documents, and Army regulations. This literature illustrated how the units used in this study were organized,

1348 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

trained and equipped. The units were then compared and contrasted to determine capability gaps within the ARSOA Gray Eagle unit. These capability gaps were based on capabilities provided by ARSOA rotary wing units that their CF counterparts were unable to provide. The same analysis was then done with the ARSOA and CF UAS units to determine whether or not ARSOA UAS provided additional capabilities like those provided by the ARSOA rotary wings units.



Research Methodology

The author used an applied professional case study methodology for the study. The applied professional case study is a method of research which is systematic, disciplined, multi-perspective, critical, and designed to both solve a problem and incorporate a research perspective. This case study will inform decision making through the rich description of the environment and recommend a policy by persuasion, reason, and evidence (Long 2016).

This research is an applied professional case study with a modified DOTMLPF-P analysis utilizing a capabilities-based assessment (CBA) to determine potential materiel and non-materiel solutions. The modified DOTMLPF-P analysis utilized the organization, training, and materiel (OTM) domains. The CBA used the professional body of knowledge in the literature review to identify capability gaps and propose material and non-material solutions. The figure and paragraphs below describe the five-chapter format used for this applied professional case study.

1349 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 3. Research Methodology Flow Chart

Source: Created by author.

In Chapter 1, the initial going-in position is captured through the first assessment in the three-part reflective process of the professional applied case study. The R1 assessment, or the initial, personal disposition on the subject is captured in this chapter. This assessment establishes the author's perspective going in and gives credibility to the research by defining what the author knew and felt about the topic prior to conducting the research, as well as establishing any pre-conceived biases going into the literature review.

In Chapter 2, the focus is to review literature from the professional body of knowledge that is both relevant to addressing the research question, and credible to the key stakeholders that the author is trying to persuade. The majority of literature for this research will come from sources within the DOD. These sources of information give the research instant credibility as they come from recognized, credible sources within the same community as the stakeholders the author is trying to persuade.

Chapter 3 describes how the study takes the "raw material" from the literature review and compares the manning, training, and equipping of the ARSOA Gray Eagle

1350 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

unit against ARSOA rotary wing units and CF UAS and rotary wing units. Once the relevant information is broken down and categorized, the study is able to conduct a CBA, focused on a modified DOTMLPF-P analysis, only utilizing the domains of organization, training, and materiel. This process will produce the results necessary to publish the findings in the next chapter.

In Chapter 4, after conducting an objective review of the literature and analyzing the relevant data, the author is able to complete the second assessment, R2. In contrast to the initial assessment, R1 in Chapter 1, the R2 assessment is an updated personal recommendation based on the author's review of the literature (Long 2016).

In Chapter 5, the study makes the final assessment, R3, that are the results from Chapter 4 examined through the lens of the pre-identified CDM and stakeholders that the study is trying to persuade. After the R3, the study takes these findings and uses the Kotter Change Model to address their implementation. Within this process, the research will also identify any new requirements that emerged as a result of the findings. Lastly, the study will address any lessons learned throughout the process. This personal reflection will also address any significant findings throughout the research that fell outside the scope of the research, but are areas that may be worth addressing in a future study.

Conclusion

This chapter provided the background and description of the applied professional case study used to answer the primary and secondary research questions. The benefit of using an applied professional case study as the methodology for this study is that it is a qualitative, complex, and human-centric topic, and it requires a deep understanding of the

1351 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

environment to produce informed decision-making. Specifically, this methodology results in compelling and supported recommendations through the process of organizing and analyzing different types of knowledge/information in a defined setting to enable informed action to improve the current conditions. In the case of this thesis, the research will result in recommendations to enhance the manning, training and equipping of the Gray Eagle company within special operations (Hancock and Algozzine 2011; Gagnon 2010). The next chapter contains the findings of the data collected within this study.

1352 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CHAPTER 4

RESEARCH FINDINGS

Introduction

The purpose of this chapter is to explain the findings of the research and to apply those findings to the applied professional case study methodology. The chapter will be broken down into three parts: the DOTMLPF-P type analysis focused on the domains of organization, materiel, training, and using the capabilities based assessment with the results expressed in the terms of a functional area analysis (FAA), functional needs analysis (FNA), and a functional solutions analysis (FSA); the R2 assessment; and a key stakeholder analysis resulting in the final assessment, R3.

Organization (Manning), Training, Materiel (Equipping) Analysis

The following table depicts the domains of organization, training, and materiel of the components that makeup the CBA, which are functional area analysis, functional needs analysis, and a functional solutions analysis.

1353 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 4. Organization (Manning), Training, Materiel (Equipping) Analysis

	ORGANIZATION	TRAINING	MATERIEL
FAA (Needs)	• Task- Provide C2 for ARSOA UAS employment IAW unit MTOE • Condition- Three simultaneous missions in separate locations • Standard- IAW ARSOA detachment C2 requirements	• Task- Provide specially selected, highly trained, ARSOA 15W operators to support special operations forces • Condition- In support of SOA missions requiring a unique skill or capability to complete. • Standard- IAW ARSOA TC 3-04.11 battle rostering requirements	• Task- Provide a UAS platform with a unique capability to support SOA • Condition- ISO SOA missions conducted outside of current MQ-1C Grey Eagle UAS capabilities • Standard- To support mission sets IAW ARSOA MTOE narrative
FNA (Gaps and Risks)	• Gap- CW4 MTOE allocation as C2 node for 3x separate locations (CONUS/OCONUS) does not meet ARSOA C2 requirements • Risk- UAS detachments in austere locations operating without commissioned, company grade C2	• Gap- ARSOA 15W operators do not have an ARSOA specific training plan or battle rostering process. • Risk- ARSOA 15W operators do not provide a unique skill or capability to support SOA.	• Gap- ARSOA MQ-1C Grey Eagle UAS platform does not provide a unique or additional capability to SOA • Risk- ARSOA MQ-1C Grey Eagle UAS unit unable to support unique SOA missions
FSA (Solution Approaches)	• Non-materiel- Increase O3 MTOE billets to 5x O3 to support C2 requirements for up to 3x simultaneous missions in separate locations • Materiel- Conduct UAS operations through use of RSO with a central MCE	• Non-materiel- Implement a BMQ, FMQ, FLD training equivalent to the ARSOA 15W operator training process.	• Materiel- Modification of MQ-1C Grey Eagle UAS to support expeditionary operations.

Source: Created by author.

Organization (Manning) Analysis

The first FAA on E/160's organization used the unit's MTOE narrative as the basis to determine the task and condition for this analysis. The MTOE narrative states that this unit has the task of supporting up to three simultaneous missions. This narrative also defines the conditions of the task by stating that the unit must be able to support these three simultaneous missions in three separate locations. In order to meet this requirement, E/160 is configured to deploy one CW4 and one E7 as the command and control node for each of the three separate locations. To determine the ARSOA command and control requirements for detached elements conducting operations, this study used a comparative analysis of the MTOE and MTOE narratives from the ARSOA rotary wing

1354 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

company, A/2-160, against the MTOE of E/160. The MTOE narrative for 2-160, which is the battalion that A/2-160 falls under, states that the battalion is not designed to deploy as a whole battalion, but rather as slice elements as part of a Joint Task Force, or as part of a Joint Special Operations Air Component. It also states that the battalion is responsible to provide up to five mission command nodes to simultaneously support split geographic locations. To support this requirement, the MTOE of 2-160 has six commissioned officers, one major and 5 captains, assigned to each rotary wing flight company. E/160's MTOE only has two commissioned officers, one major and one captain. This analysis was used to establish the criteria for commissioned officers in the grade of captain or above and was the standard for geographically dispersed detachment command and control requirements. Additionally, the majority of the battalions in the 160th SOAR mirror the MTOE of 2-160, which reinforced the standard used during the FAA. Importantly, the personal experience of the author attests that CW4s do not serve in a command and control capacity within the 160th SOAR at geographically dispersed locations.

The FNA took the analysis from the FAA to determine any potential capability gaps in the organization of the unit. The first premise that determined the gap in the organization of E/160 was the MTOE comparative analysis. The ARSOA rotary wing companies are manned with an appropriate amount of commissioned officers in the rank of O3 and above to support the detachment command and control requirement as stated in their MTOE narrative. E/160 is manned with CW4s to fulfill their command and control requirement for three geographically dispersed missions. This analysis concludes that the 160th SOAR requires commissioned officers in the rank of O3 and above to act as the

1355 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

command and control elements of geographically dispersed detachments, and identifies a gap in E/160's organization, as E/160 is not able to organically support three geographically dispersed missions with an O3 or above as the command and control element.

This capability gap results in operational risk because it does not give E/160 the organic capability to conduct three geographically dispersed mission sets with a command and control element that meets the requirements of the 160th SOAR. Additionally, this presents risk in the mission approval process for aviation operations at geographically dispersed locations. The final portion of the aviation mission approval process requires the signatures of a mission briefing officer (MBO) and a final mission approval authority (FMAA). The FMAA is the individual that assumes the overall risk of the mission, and assuming risk is primarily the responsibility of commanders in the grade of O3 and above. A CW4 can have FMAA, but it is not the normal process for aviation operations and for that reason it is not included in this analysis of the risk.

The FSA identified a materiel and non-materiel solution to this capability gap. The non-materiel solution would re-allocate MTOE personnel billets of existing human resources in order to fill this capability gap and ensure no increase to the current E/160 MTOE of 165 personnel. The proposed solution would change the five CW4 personnel billets on E/160's MTOE to the grade of O3. This would change paragraph number 102, line number 01, UAS OPERATIONS OFFICER and paragraph number 105, line number 01, UAS PLATOON LEADER, from CW4 allocated billets to O3 billets, which would add five additional O3s to E/160's MTOE. This change would align E/160's MTOE to mirror the rotary wing companies' MTOEs that have six O3 MTOE billets each. This

1356 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

solution would enable E/160 to organically provide a command and control element with an O3 or above to support three geographically dispersed locations at a 1:2 deployment ratio.

The proposed materiel solution to this capability gap would be for E/160 to conduct remote split operations (RSO). RSO would solve this capability gap by providing a central mission control element (MCE) at E/160's home station to provide command and control of three geographically dispersed locations. E/160 would have two commissioned officers in the grade of O3 and above to provide command and control of three launch and recovery elements (LRE) at three geographically dispersed locations. This is a materiel solution because it would require an investment to the current communications architecture in order for E/160 to conduct RSO.

The second FAA on E/160's organization used Army doctrine, *ADRP 3-05 Special Operations,* and Joint doctrine, *JP 3-05 Special Operations,* to establish the task for this analysis. Of note, the author did not include this second analysis in the table at the beginning of this chapter because while the following analysis is relevant and identified a follow-on research question in chapter five, it did not make it past the author's updated individual recommendation and would not be brought before the CDM in the R3. These guiding doctrinal references state that in order to be a special operations unit, the unit must be specially organized, trained, and equipped. The FAA task in terms of organization is that E/160 must have more senior and experienced 15W Gray Eagle operators. Army and Joint doctrine also provide the condition for this analysis, that E/160 must be able to provide special operations forces with a unique capability in terms of employment, tactics, techniques, procedures, and equipment. An increase in the grade of

1357 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

15Ws assigned to E/160 would provide this unique capability, differentiating E/160 from conventional MQ-1C Gray Eagle units. To determine the standard for the FAA, this study used an MTOE comparative analysis of ARSOA rotary wings units to CF rotary wing units and compared them to ARSOA Gray Eagle in relation to CF Gray Eagle formations. This established the standard set for this study. The graphs below illustrate that airframe operators, in this case MH-47/CH-47 pilots and MQ-1C Gray Eagle 15W operators, are more senior in ARSOA rotary wings units compared to CF rotary wing units, but that is not the case for ARSOA Gray Eagle operators.

The number of personnel must be taken into account when viewing this graph since the ARSOA units have a higher overall number of personnel assigned than the CF units.

Table 5. Operator and Pilot Analysis

MQ-1C OPERATORS BY GRADE	E/160TH SOAR	B/101ST ABN
E-7	4	3
E-6	8	6
E-5	16	9
E-4	24	16

H-47 PILOTS BY GRADE	A/2-160TH SOAR	B/3-82ND
W4	8	0
W3	13	3
W2	0	17

Source: Created by author.

The A/2-160's MTOE total is 139 personnel, compared to B/3-82's MTOE of 52 personnel, and E/160's MTOE total of 165 personnel, compared to B/101's MTOE of

1358 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

127 personnel. Even with the overall MTOE number taken into account, it is clear that A/2-160 has more senior pilots than B/3-82. A/2-160 has no CW2s assigned while the majority of pilots assigned to B/3-82 are made up of CW2s. Conversely, B/3-82 has zero CW4s assigned while A/2-160 has eight. When looking at the MTOEs of E/160 and B/101, the same differences are not evident. When the difference in overall MTOE personnel assigned is taken into account, the operators by grade are essentially the same for E/160 and B/101. Since the overall majority of ARSOA has MTOEs that mirror A/2-160, this analysis determined that the standard for ARSOA is to have more senior pilots and operators than the CF counterparts.

The FNA took the analysis from the FAA to determine any potential capability gaps in the organization of the unit. The first premise that determined this gap in E/160's organization was the MTOE comparative analysis. The ARSOA rotary wing companies are manned with pilots of a higher grade than the CF rotary wing units. This comparison illustrated a gap in E/160's capability because when compared to the MTOE of B/101, the operator by grade, is essentially the same. This is a capability gap, because E/160 is not specially manned to support special operations, as compared to ARSOA units.

This capability gap results in operational risk by not providing a unique capability in terms of organization to special operations because E/160 does not have more senior Gray Eagle operators than CF Gray Eagle units. Part of ARSOA's ability to provide a unique aviation capability to special operations is by manning the rotary wing units with more senior pilots to conduct ARSOA missions. ARSOA mitigates risk and is able to conduct operations that CFs are unable to accomplish, in part, because ARSOA has deliberately organized its rotary wing units with senior grade pilots. E/160 does not have

1359 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

this same organization, which increases the risk of conducting unique missions in support of special operations.

The FSA used the analysis of the ARSOA rotary wing unit, A/2-160, presented in this study, as the basis for the recommended materiel solution. The materiel solution would be to increase MTOE billets of the enlisted Gray Eagle 15W operators in the grades of E5, E6, and E7. This solution would not add additional personnel to E/160's overall personnel count of 165, but would take those billets from the E4 15W billets. This change is in line with the organization of A/2-160, as that unit's pilot billets have no CW2s, and only have MTOE billets in the grade of CW3 and above. The increase of E5, E6, and E7 15W MTOE billets would increase the overall experience level of 15W operators to match the capabilities provided by ARSOA rotary wing units. Additionally, increasing E7 15W MTOE billets within E/160 will enable experienced operators to remain within the unit, increasing the unit's capability. Currently, E/160 only has four E7 15W MTOE billets, as UAS PLATOON SERGEANTS, that focuses those E7 15W operators on the leadership and administrative requirements of the platoon. In comparison, A/2-160 has CW4 MTOE billets at the platoon level as SR IP/IFE, which is a position that focuses on the tactical employment of the MH-47G. This analysis illustrates that ARSOA rotary wing units have MTOE billets that enable their most experienced pilots to remain at the platoon level that adds a unique capability in terms of organization and manning, that the CF does not. This materiel solution to E/160's manning would enable them to provide the same capability as the ARSOA rotary wing units.

1360 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Training Analysis

The FAA on E/160's training also used Army doctrine, *ADRP 3-05 Special Operations,* and Joint doctrine, *JP 3-05 Special Operations,* to establish the condition for analysis focused on distinctive capabilities required of special operations forces. This study used the unique ARSOA mission battle-rostering requirements in accordance with *ARSOA 3-04.11* as the basis for the standard in the FAA. This standard determined that battle-rostering within special operations aviation is unique and ensures the ground force commander has support by providing a clear tool to control risk while retaining mission flexibility. ARSOA accomplishes this through its unique battle-rostering, which organizes crews by mission qualification.

The FNA took the analysis from the FAA to determine potential capability gaps in unit training. The analysis determined that E/160 does not have an ARSOA specific mission training process for 15W Gray Eagle operators. The ARSOA rotary wings units have a unique training and battle-rostering process that uses the aircrew mission designations of BMQ, FMQ, and FLD to provide a unique, special operations specific, capability. E/160 uses the same battle-rostering process as conventional Gray Eagle units and does not have unique, special operations aviation specific aircrew designation of BMQ, FMQ, and FLD. This study used this analysis to define this as a training capability gap within E/160.

The risk associated with this capability gap is that there is an expectation from supported special operations forces that ARSOA provides a unique Gray Eagle capability, and part of that expectation involves uniquely trained 15W operators. This expectation is determined by both the doctrinal definition of a special operations unit and by the precedent set by ARSOA rotary wing over the past 36 years. ARSOA rotary wing

1361 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

units use their unique battle-rostering process to reduce risk for the ground force commander during aviation operations. Without a unique, mission tailored battle-rostering process, E/160 cannot provide the same risk reduction capability to the ground force commander that the ARSOA rotary wing units provide.

The FSA used the unique ARSOA rotary wing mission training process as the basis for this solution. The proposed non-materiel solution to this capability gap would be for E/160 to implement an ARSOA specific 15W operator training and mission battle-rostering process that mirrors the ARSOA rotary wing units. This would include adding additional aircrew designations, like BMQ, FMQ, and FLD, to the unit's aircrew training programs that would enable E/160 to battle-roster their crews to tailor specific mission requirements. This would enable E/160 to provide a unique special operations Gray Eagle capability to the ground force commander that would enable them to control risk while retaining mission flexibility.

Materiel (Equipping) Analysis

The FAA related to materiel (equipping) also used Army doctrine, *ADRP 3-05 Special Operations,* and Joint doctrine, *JP 3-05 Special Operations,* to establish the task for analysis focused on distinctive capabilities required of special operations forces. To define the standard for the FAA, this study used a comparative analysis of the airframe operator's manuals from the different units included in this study. This comparison illustrated that the ARSOA rotary wing unit, A/2-160, has a modified version of the CF Army CH-47F Chinook, heavy lift rotary wing. A/2-160 employs the MH-47G Chinook, a heavy assault rotary wing which provides special operations forces with a unique piece of equipment that provides additional capability to special operations. For example, the

1362 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

MH-47G has an in-flight refuel capability that provides special operations forces with a long-range infiltration capability not provided by the CF's CH-47F. When this same comparison is made between the ARSOA and CFs Gray Eagle units, there is no specialized equipment that enables E/160 to provide an additional capability to special operations forces. The Gray Eagle employed by E/160 is identical to the one employed by the CF Gray Eagle unit, B/101. Given the results of this comparison, this study then used the MTOE narrative of the ARSOA rotary wing units to define the standard that states the unit has unique equipment, tailored to support specific mission profiles.

The FNA used the analysis from the FAA to determine any potential capability gaps in the equipping of the unit. The analysis determined that E/160 does not have equipment that provides a unique capability to the ground force commander like the ARSOA rotary wing units. To further define the possible equipment capability gaps, this study used three unique capabilities provided by ARSOA rotary wing units in comparison to CF's rotary wing units. These capabilities are extended range, advanced aircraft survivability equipment, and advanced onboard radar allowing rotary wing operations in degraded environmental conditions. These equipment capabilities provide a unique capability to support the ground force commander over those that exist within the conventional forces (CF). This illustrates an equipment capability gap for E/160, because their equipment does not provide a unique capability in comparison to the CF Gray Eagle units.

The risk associated with the identified equipment capability gap is that E/160, in terms of UAS support, does not offer the ground force commander a unique capability to execute missions that are outside of the CF's Gray Eagle capability. Special operations

1363 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

require a unique equipment capability because they are often conducted in denied or hostile environments, under unfavorable weather and environmental conditions, and require real time intelligence. As an intelligence, surveillance, and reconnaissance platform in support of special operations, E/160 has to have a unique capability that can operate in conditions that exceed the ability of those found in the CF units.

The FSA used the unique capabilities provided by the ARSOA rotary wing units as the basis for this solution. The proposed materiel solution would be for ARSOA to invest in research and development to modify the Gray Eagle to provide a unique UAV platform capability specifically designed to support the special operations community. The specific modifications should be the focus of a follow-on study; however, based on the author's operational experience, the author would recommend two potential materiel solutions to the current Gray Eagle company equipment resources to enhance its ability to support special operations. First, the engineers should reduce the size of the ground control station, satellite and ground data terminals, and secondly, they should reduce the total amount of ground support equipment required to operate the Gray Eagle to improve the company's expeditionary capability.

R2: The Updated Individual Recommendation

The R2: Updated Individual Recommendation is composed of the same questions that were answered in the R1: Initial Personal Recommendation. The difference is that these same questions will be answered after conducting the literature review. This illustrates the changes in opinion and recommendation after completing a review of the relevant literature. The R2 provides credibility to the applied professional case study methodology by demonstrating to the reader the changes in perception by the author after

1364 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

completing the literature review. The R2: Updated Individual Recommendation will only address significant changes from the R1: Initial Personal Recommendation.

The first part of the R2 discusses the primary research question and why it is important to the author and the key stakeholders within the United States Army Special Operations Command (USASOC). When this research effort was initiated the primary research question in this study was framed as: how should United States Special Operations Command adapt manning, training, and equipping of the ARSOA Gray Eagle unit to provide the unique capabilities required by the special operations community? Joint and Army doctrine both define special operations as activities requiring unique capabilities not provided by the CF. Doctrine also affirms that special operations forces must be specially organized, trained, and equipped to provide this unique capability (ADRP 3-05, 2012; JCS 2011). After analyzing the similarities and differences of a CF Gray Eagle company to an ARSOA Gray Eagle company and comparing them to the similarities and differences between a CF rotary wing company and an ARSOA rotary wing company, it is evident that there are gaps in capabilities provided by the ARSOA Gray Eagle company. Specifically, the manned ARSOA rotary wing company analyzed in this study provides unique special operations capabilities because it is specifically manned, trained, and equipped differently than the CF rotary wing company analyzed in this study. However, the same cannot be said about the ARSOA MQ-1C Gray Eagle company in comparison to the CF MQ-1C Gray Eagle company. This new knowledge and understanding led the author to update the primary research question to: are there organizational (manning), training, and materiel (equipping) capability gaps that are

1365 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

preventing the ARSOA Gray Eagle unit from providing a unique special operations aviation capability?

During the course of this study, the author was informed that upon completion of the Command and General Staff College, he would be taking command of the newly fielded ARSOA Gray Eagle company, Company F, 160th Special Operations Aviation Regiment, scheduled to officially activate in August of 2018. In turn, this made the author a stakeholder in this research at the tactical level and more invested than at the beginning. The review of literature also defined the stakeholders' position and established the basis that the CDM will evaluate this study through the R3: Stakeholder Recommended Solution, presented in the final assessment.

The second part of the R2 addresses why this study is important and the possible consequences if this topic is not addressed. The new ARSOA Gray Eagle company, F/160, is scheduled to activate in August 2018 and results in the fielding of two ARSOA Gray Eagle companies within a five-year period. This highlights the importance that the DOD is placing on the development of UAS within ARSOA. The review of literature confirmed the author's initial position and opinion that the UAS capability provided to special operations aviation must provide a unique capability not provided by the CF Gray Eagle units. Additionally, the earlier that these gaps can be identified and validated by the CDM, the earlier the solutions can be implemented.

The final portion of the R2 identifies the potential solutions to the problem statement identified through the review of literature. The review of literature identified gaps within the manning, training, and equipping of the ARSOA Gray Eagle company. The primary sources of data for this study were DOD publications. The MTOE

1366 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

documents for the four units used in this study provided a clear comparison of the CF and ARSOA Gray Eagle companies in relation to the ARSOA and CF rotary wing companies. This analysis provided evidence to support a capability gap in the manning of the ARSOA MQ-1C Gray Eagle company. The MTOE narrative and aircrew training publications provided the necessary information to compare and contrast the training requirements and processes within the different ARSOA and CF companies used in this study. This provided insight on gaps within the training domain of the ARSOA Gray Eagle company. Lastly, by comparing airframe specific technical manuals, it was evident that there was no unique equipping capability provided by the ARSOA Gray Eagle company in comparison to the CF's UAS company. In contrast, by comparing the airframe specific technical manuals of the ARSOA and CFs rotary wing companies, ARSOA aircraft provided a unique equipping capability when compared to the CF's. By identifying these gaps and the risks associated with them, the potential materiel and non-materiel solutions for each were identified and explained earlier in this chapter.

R3: Stakeholder Recommended Solution

To determine the R3: Stakeholder Recommended Solution, the author evaluated the R2 through the lens of the Chief Decision Maker (CDM) and the stakeholders. The CDM for this applied professional case study is the Commander of the United States Army Special Operations Command (USASOC), the stakeholders include the 160th SOAR Regimental Commander, and to a smaller extent, the 160th SOAR Battalion Commanders. The USASOC Commander was chosen as the CDM as opposed to the Commander of United States Special Operations Command (USSOCOM) because the purpose of this applied professional case study is to persuade the CDM in order to affect

1367 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

change. The USSOCOM Commander already employs Group 4 UAS within the other services, but this study is specific to employment of the Gray Eagle within ARSOA, which is focused on the Army and its mission of unified land operations, "to apply land power as part of unified action to defeat an enemy on land and establish conditions that achieve the JFC's commander's end state" (FM 3-0 2017, 34; USSOCOM Fact Book 2017, 49). This means that the USASOC Commander must be persuaded that the ARSOA Gray Eagle needs to provide a unique UAS capability to enhance ARSOA before these potential solutions are presented to the USSOCOM Commander.

ARSOF 2022 and *USASOC Strategy-2035* comprised the literature used as the basis for the CDM's concerns. Additionally, the concerns presented were compared to the 2018 USSOCOM Posture Statement made by the Commander, General Raymond A. Thomas, on February 15, 2018 before the House Armed Services Committee, to ensure that these concerns are nested within the next higher echelon of command. The main concerns of the CDM were to:

- Obtain next generation unmanned aircraft systems that provide longer operational range, over horizon observation, and can be launched and recovered by tactical units;
- Employ advanced unmanned aircraft systems and intelligence collection capabilities at the tactical level; provide joint force commanders with professionals who are agile, adaptive, flexible, bold, innovative, and possess a high degree of advanced training;
- Provide the nation's premier special operations forces, delivering appropriate and effective capabilities to joint force commanders and interagency leaders across the entire spectrum of conflict and under any operating conditions;
- Broaden the range of special operations aviation-related individual training and education including unmanned aircraft systems; and
- Improve army unmanned aircraft system programs of record (Raven, Shadow and Gray Eagle) to meet joint expeditionary tactics, techniques, procedures, forward-

1368 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

based networking, and sensor requirements (HQDA 2014a, 24; ARSOF 2035 2017, 3-6).

The first part of the R3 will discuss the primary research question and why it is important to the CDM, the Commander of United States Army Special Operations Command (USSOCOM). The primary research question for this study is: are there organizational (manning), training, and materiel (equipping) capability gaps that are preventing the ARSOA Gray Eagle unit from providing a unique special operations aviation capability? The primary research question in this study is directly in line with the CDM's position because it specifically addresses the objectives for improved UAS capabilities within special operations as defined in *ARSOF 2022* and *USASOC Strategy-2035*. However, the CDM would disagree with the premise that E/160 does not provide a unique special operations aviation capability. The CDM would argue that the unique capability provided by E/160 is that it is manned and equipped to support three geographically dispersed mission sets simultaneously, as stated in the MTOE narrative, "this unit was specifically designed to meet SOA requirements for multiple simultaneous deployments to widely separated areas." From a manning perspective this is clearly evidenced by E/160's MTOE total of 165 personnel, compared to B/101's MTOE of 127 personnel. However, from an equipping perspective, both E/160 and B/101 are supplied with the same amount of equipment that makes up the UAS company; 12 x unmanned aerial vehicles (UAVs), 6 x ground control stations (GCSs), 6 x ground data terminals, and 3 x satellite ground data terminals. E/160 is equipped with slightly more ground support equipment, specific to the UAS, and has three additional generators. This means that from a purely equipment perspective, B/101 could support three geographically dispersed mission sets simultaneously, just like E/160.

1369 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The second part of the R3 addresses why this study is important and the possible consequences if this topic is not addressed. In contrast to the author, the CDM would have to take into account competing resources when reviewing the results of this study. The CDM is responsible for a much bigger organization than what the author addresses in the R2, meaning that this study would have to persuade him to believe that the capability gaps addressed in this study outweigh other requirements in the USASOC enterprise. This would make the consequences to the CDM very different than the consequences stated by the author, while acknowledging that the CDM may face other consequences in the USASOC enterprise by electing to use valuable resources to pursue any of these proposed materiel solutions.

The final portion of the R3 takes the recommended solutions from this study and filters them through the lens of the CDM. The first organizational (manning) capability gap identified in this study was the lack of commissioned, company grade and above officers to perform the command and control requirement for three geographically dispersed mission sets. The two recommended solutions to this capability gap were to conduct RSO or to increase the O3 MTOE billets to six. The CDM views RSO as a viable option for ARSOA to employ its Gray Eagle assets. The author's personal operational experience attests that DOD conducted a study into RSO for ARSOA, but due to classification cannot disclose the findings or implications for future ARSOA employment.

The second recommended solution, to increase O3 MTOE billets, would not be accepted by the CDM for two reasons. First, this solution does not address any of the CDM's chief concerns. Second, it would not be feasible with respect to personnel

1370 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

limitations within ARSOA. Additionally, E/160 is attached to 2d Battalion, 160th SOAR, that the CDM would argue has the ability to support E/160 with its O3 command and control requirements to support three simultaneous, geographically dispersed missions. The second organizational (manning) gap addressed by the author was the need to increase the 15W MTOE billets of E5, E6, E7, and to reduce the number of E4s. The CDM would not approve this solution because it does not fall within his main concerns. The CDM is concerned with broadening the range of special operations aviation-related individual training and education including unmanned aerial systems, and would invest in that as opposed to the additional cost of increasing the rank structure of the 15Ws.

The training capability gap addressed in this study is that E/160 does not have an ARSOA specific mission training process for 15W Gray Eagle operators. The proposed non-materiel solution to this capability gap would be for E/160 to implement an ARSOA specific 15W operator training and mission battle-rostering process that mirrors the ARSOA rotary wing units. The CDM would approve this proposed solution because it meets all the criteria of an FSA, is non-materiel, and is in-line with his concern of broadening the range of special operations aviation-related individual training and education including unmanned aerial systems.

The materiel capability gap addressed in this study is that E/160 is not equipped to provide a unique ARSOA UAS capability. The proposed materiel solution would be for ARSOA to invest in research and development to modify the Gray Eagle to provide a unique aviation capability. The author recommended a modification to the Gray Eagle that increases its expeditionary capability by reducing the physical size of the ground control station, and satellite and ground data terminals as well as reducing the total

1371 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

amount of ground support equipment required to operate the Gray Eagle. The CDM would agree with the author's recommendation to conduct research and development into the modification of the Gray Eagle to increase its expeditionary capability. This recommendation is in-line with the CDM's concern of improving Army unmanned aircraft-system programs of record (Raven, Shadow and Gray Eagle) to meet joint expeditionary tactics, techniques, procedures, forward-based networking, and sensor requirements.

Conclusion

This chapter explained the findings of the research and applied those findings to the applied professional case study methodology. The modified DOTMLPF-P analysis provided recommended solutions to the CDM through the use of a CBA. These proposed solutions were then vetted by the CDM, through the final assessment, the R3. The next chapter, Chapter 5, will address the final recommendations of this study.

1372 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CHAPTER 5

CONCLUSIONS AND RECOMMENDATIONS

Recommended Solutions

This section will discuss the implementation plan for the two recommended solutions proposed by this study. The implementation plan is broken down into short term (one to two years) and long term (three to five years) time frames and will use the principles of the Kotter Change Model for implementation. The two proposed solutions are a direct result of the author's professional operational experience in ARSOA, extensive literature review based in the professional body of knowledge that exists for this topic, and the analysis of that knowledge through the use of the applied professional case study methodology.

The United States Army is an organization that is not always willing to acknowledge and embrace the need for change. There are many ways to accomplish change within an organization and one that is both appropriate for this study and used in Army doctrine is the Kotter Change Model, hereafter referred to as the Kotter Model. This model uses the following eight-step process to affect change within an organization.

The first step in the Kotter Model is to establish a sense of urgency. This is done by creating a climate within the organization that is dissatisfied with the status quo by setting aggressive goals and objectives that force the organization to make significant change and overcome complacency.

The second step is to create the guiding coalition. After establishing a sense of urgency, a group of senior, influential, and respected individuals within the organization

1373 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

that support and are fully committed to implementing the change must be formed to propel the change forward.

The third step is to develop a vision and a strategy. Once the guiding coalition is formed, that group is used to develop a feasible vision and strategy that is imaginable, desirable, feasible, focused, flexible, communicable, provides an imaginable picture of the future, a shared sense of purpose, focuses efforts, aligns priorities, and sparks excitement for members of the organization.

The fourth step is to communicate the change vision. This is one of the most important stages within the process. Simply creating a vision and strategy to affect change accomplishes nothing unless the entire organization knows what the vision is and why it is so important for the organization to undertake.

The fifth step is to empower broad-based action. This involves empowering subordinate leaders that are committed to the change, potentially removing leaders that oppose it, creating an environment of decentralized control, and developing a shared understanding with mutual trust.

The sixth step is to generate short term wins. These accomplishments enable the organization to see tangible results toward accomplishing the desired change, which in some cases could take years to complete. Identifying and rewarding these short term gains helps to maintain the momentum of the change effort.

The seventh step is to consolidate gains and produce more change. Consolidating the effects garnished from the short terms wins will open the change initiative to other areas within the organization that were not evident at the start of the change process.

1374 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Identifying these other changes and capitalizing on them during the process is essential to preventing regression while maintaining the momentum for further change.

The eighth and final step is to anchor the new approach into the culture. Kotter defines culture as, “norms of behavior and shared values among a group of people”. This final step is vital as it is the point where the organization as a whole, believes that the new process is the way the organization now does business and ensures the practice remains even if the current leadership at the time of the change, switches out (Miller and Turner 2017, 1-8)

The proposed solution identified for short term implementation (one to two years) is to implement an ARSOA-specific 15W operator training and mission battle-rostering process that mirrors the ARSOA rotary wing units. This change to the training domain of ARSOA Gray Eagle units would be a fairly simple change to make. This is because the process for this type of training plan is already in place for the ARSOA rotary wing units. This is a mission specific training program and could theoretically be implemented with minimal increase to the individual operator required flight hours. Affecting this change would not necessarily have to be approved by the Chief Decision Maker (CDM), but could be implemented by the other stakeholders, most likely by the 160th SOAR Commander. Additionally, because this is a non-materiel solution, it is very realistic for short term implementation. This proposed solution was recommended because it is nested within the main concerns of the CDM, as stated in *ARSOF 2022* and *USASOC Strategy-2035*, that include: (1) provide joint force commanders with professionals who are agile, adaptive, flexible, bold, innovative, and possess a high degree of advanced training, and

1375 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

(2) broaden the range of special operations aviation-related individual training and education including unmanned aircraft systems.

Using the principles of the Kotter Model, the author recommends the following short term implementation plan for the proposed change to the training domain of the ARSOA Gray Eagle units. It is once again important to note that the author will be taking command of the newly fielded ARSOA Gray Eagle company, F/160, with an activation date set for August 2018, and will attempt to affect this proposed change to the training domain of F/160. The author's professional operational experience attests that the biggest obstacles to implementing this change will be with steps one and two of the Kotter Model. The first ARSOA Gray Eagle company, E/160, is viewed as a critical capability within the SOF community, and because of that, the author believes that establishing a sense of urgency, as well as forming a guiding coalition will be difficult. The argument to overcome this is that the ARSOA rotary wings success over the past 36 years is directly attributed to this process of training. Additionally, because this process is already in use by the ARSOA rotary wing units, step three of the Kotter Model will be extremely easy to produce, since it already exists. That is also why the author believes that this recommendation is so viable, because the organization has already bought into the process and can easily identify with it. The challenge will be in convincing the other stakeholders, as well as the senior members of the unit, that this process can be as beneficial for the ARSOA Gray Eagle community as it is for the ARSOA rotary wing community.

After garnishing support for this recommended change, the next biggest task will be to generate short term wins in order to ensure this change gains momentum and

1376 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

becomes part of the established training process within the organization. The immediate result of applying this training process within the organization, will be the increased confidence that the individual operators will have when conducting their mission and specifically with their ability to conduct professional air mission briefs. The ARSOA mission training process involves extensive training in the process of conducting professional military air mission briefings. Making that a part of the ARSOA 15W training process will dramatically increase their confidence in their briefing abilities and propel this change forward from the bottom up. With a bottom up approach, this will ensure the majority of the company buys into the new training process which will help to confirm this solution with the organization's leadership and stakeholders.

Once the recommended training process is established at the company level, this implementation plan will look to consolidate gains and further the change process by establishing this recommended change at the battalion and regimental levels. To accomplish this, the training process will first need to be standardized within the battalion and then, to anchor the change, written into the regimental standard operating procedure. Once the process is refined and standardized enough to be written into the official regimental standing operating procedure, it will ensure that this process is the approved way that the organization does business, and will remain in place once the implementing leadership switches out.

The proposed solution identified for long term implementation (three to five years) would be for ARSOA to invest in research and development to modify the Gray Eagle to provide a unique aviation capability to the SOF community. It is important to note that this recommendation was selected for long term implementation because

1377 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

ARSOA is currently scheduled to conduct the full operational testing and evaluation of the MQ-1C Gray Eagle Extended Range UAS in July of 2018. This new version of the Gray Eagle will provide additional capabilities and, because of this, it is unlikely that the CDM will have an appetite for any additional investment into research and development of the Gray Eagle until the added benefits of this new version are fully understood. It is also important to note that while ARSOA is conducting the full operational testing and development of the MQ-1C Gray Eagle Extended Range UAS, this new version will be fielded to both ARSOA and CF Gray Eagle units and the new capability will not be unique to the SOF community.

The specific modification to the Gray Eagle should be the focus of a follow-on study. Based on the author's operational experience, the author would recommend a modification that would increase its expeditionary capability, specifically by reducing the size of the ground control station, satellite and ground data terminals, and reducing the total amount of ground support equipment required to operate the Gray Eagle. This proposed solution was recommended because it is nested within the main concerns of the CDM, as stated in *ARSOF 2022* and *USASOC Strategy-2035*, that include: (1) obtain next generation unmanned aircraft systems that provide longer operational range, over horizon observation, and can be launched and recovered by tactical units, and to (2) improve army unmanned aircraft system programs of record (Raven, Shadow and Gray Eagle) to meet joint expeditionary tactics, techniques, procedures, forward-based networking, and sensor requirements.

Using the principles of the Kotter Model, the author recommends the following long term implementation plan for the proposed change to the materiel domain of the

1378 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

ARSOA Gray Eagle units. Unlike the proposed short term solution, the identified long term solution is simply a recommendation to invest in research that will lead to a change in the future. For this reason, the implementation plan will not use all eight steps of the Kotter Model, but will focus on Steps One and Two. The author believes that creating a sense of urgency and building a guiding coalition among the CDM and stakeholders for this recommended solution will be difficult, given the fact that a new version of the MQ-1C Gray UAS is currently being fielded. The key to overcoming this obstacle is to emphasize to the CDM and stakeholders the fact that the new version of the Gray Eagle was based upon the needs of the CF, and that a SOA specific research and development process has not been conducted to meet SOF specific UAS needs. This will remain in line with ARSOA common practice, as the rotary wings employed by ARSOA were modified based on SOF specific operational needs, and that the same should hold true for the platform employed by the ARSOA UAS units.

Recommendations for Further Study

The first recommendation for further study would be to increase the expeditionary capability of the Gray Eagle by reducing the size of the ground control station, satellite and ground data terminals, and the amount of ground support equipment required to operate the Gray Eagle. The study would need to focus on the current breakdown and buildup times of the Gray Eagle in its current configuration as well as the amount of pallet space aboard United States Air Force (USAF) aircraft that is required to move one Gray Eagle flight platoon from one location to another. The study would then need to establish the timeline and cargo requirements needed to support United States Special Operations Command (USSOCOM) type of mission sets. Once this baseline is

1379 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

established, the study would be able to determine the specific requirements needed to publish the Operational Needs Statements (ONS) request to industry leaders and produce a modified version of the Gray Eagle to address the capability gap in supporting this USSOCOM mission set.

The second recommendation for further study would be to further research the capability provided by using Remote Split Operations (RSO) to employ ARSOA UAS. As stated earlier in this thesis, the professional operational experience of the author attests that there has been a study conducted on RSO, but due to classification cannot publish the results. However, the author would argue that another study needs to be conducted looking specifically at the benefits gained by the communication architecture needed to conduct RSO. In addition to the expeditionary and manning benefits of RSO, the author believes that RSO would also benefit the training level of 15W operators.

Affording 15W operators different training environments is difficult due to the fact that UAS operations within the national airspace are very hard to conduct. Currently, the process involved with transiting the national airspace with a UAV is next to impossible because of the restrictions imposed by the Federal Aviation Administration (FAA). This forces ARSOA Gray Eagle units to exclusively train at their home base or incur the high costs of transporting all the equipment necessary to operate at another US location. The author believes that these costs could be greatly reduced by the infrastructure associated with conducting RSO, which would make training at different locations within the United States more of a reality. The study would need to look at a cost analysis of being able to move a relatively small UAS package, due to the communication architecture of RSO, from one location to another, in order to train with

1380 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

different SOF units across the United States. The author believes that by conducting this analysis, the CDM and stakeholders would see another benefit of RSO that has not been previously addressed.

The final recommendation for further study would be to further research small precision guided munitions. The Gray Eagle needs to have the ability to tailor its payload based on the mission set. Weight will always be a factor regarding UAS operations and further research needs to be conducted to find an alternate payload for the Gray Eagle other than its current restriction to the Hellfire missile. This is not to say that the Hellfire is not an effective munition for the Gray Eagle, but in its current configuration, it can only carry up to four Hellfire missiles. This recommendation for further study would be to give the Gray Eagle an alternate, lighter, precision guided munition that would provide the ground force commander with more options when supporting different mission sets.

In addition to the aforementioned recommendations, the author and his thesis committee members developed four additional recommendations for further study after conducting the formal thesis defense. The four recommendations for further study are: (1) What are the training requirements that will be driven by an upgraded Gray Eagle materiel solution? (2) Perform a manpower grade analysis to document personnel requirements in the grades of O3 and CW4, for six MTOE positions. (3) Determine if ARSOA manning policy needs to be amended to account for UAS needs. (4) Conduct a SOF specific mission analysis for UAS platforms to define materiel key performance parameters.

1381 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Personal Learning Reflections

By conducting this research, the author gained a clear understanding of the current capabilities of the ARSOA Gray Eagle units, and more importantly, an understanding of the current capability gaps in the domains of organization, training, and materiel. As a future stakeholder in this community, this research enabled the author to develop a vision and strategy for commanding the newly fielded ARSOA Gray Eagle company, F/160. Additionally, by focusing this study within the professional body of knowledge associated with this topic, the author was able to both confirm and reject various biases that were held prior to conducting this study. This is significant, as the applied professional case study methodology ensured that the author's understanding of this topic moving forward is objective and based solely on the credible literature that was reviewed during the study.

In addition to his own professional growth, the author believes that this study is the first step for the ARSOA UAS community to begin to define its role within SOA. The Gray Eagle platform was designed to meet the needs of the CF and this paper has illustrated the fact that while this current capability is successful in ARSOA, it is now at the point where ARSOA needs to modify the current capability for SOA. Just like the ARSOA rotary wing units took CF rotary wing organizations and modified them to meet SOA specific needs, the ARSOA Gray Eagle units need to begin making the same organizational, training, and materiel modifications to support specific SOA needs.

14. ABSTRACT

The Army began the testing and development of the unmanned aircraft system (UAS) capability in 1953. Since that point, the UAS has grown exponentially and proven itself as an essential capability on the battlefield in every major conflict since Desert Storm. In 2013, the United States Army Special Operations Command (USASOC) began to employ the first and only Special Operations Aviation (SOA) MQ-1C Gray Eagle UAS unit in the Army. The Army Special Operations Aviation (ARSOA) Gray Eagle unit is organized, trained, and equipped in an almost identical fashion as the conventional force (CF) Gray Eagle units. Conversely, the rotary wing units within ARSOA are organized, trained, and equipped in a very different manner than the CF rotary wing units.
The purpose of this study is to illustrate that capability gaps exist in the domains of organization, training, and equipping of the ARSOA Gray Eagle unit. A comparative analysis of ARSOA rotary wing units in relation to CF rotary wings is used to identify these capability gaps. The study then uses a modified doctrine, organization, training, materiel, leadership and education, personnel, facilities, policy (DOTMLPF-P) analysis and a capabilities-based assessment (CBA) to identify potential materiel and non-materiel solutions.

ABSTRACT

THE FIRST STEP: BUILDING A SPECIAL OPERATIONS AVIATION SPECIFIC UNMANNED AIRCRAFT SYSTEM CAPABILITY, by Joshua J. Durham, 84 pages.

The Army began the testing and development of the unmanned aircraft system (UAS) capability in 1953. Since that point, the UAS has grown exponentially and proven itself as an essential capability on the battlefield in every major conflict since Desert Storm.

In 2013, the United States Army Special Operations Command (USASOC) began to employ the first and only Special Operations Aviation (SOA) MQ-1C Gray Eagle UAS unit in the Army. The Army Special Operations Aviation (ARSOA) Gray Eagle unit is organized, trained, and equipped in an almost identical fashion as the conventional force (CF) Gray Eagle units. Conversely, the rotary wing units within ARSOA are organized, trained, and equipped in a very different manner than the CF rotary wing units.

The purpose of this study is to illustrate that capability gaps exist in the domains of organization, training, and equipping of the ARSOA Gray Eagle unit. A comparative analysis of ARSOA rotary wing units in relation to CF rotary wings is used to identify these capability gaps. The study then uses a modified doctrine, organization, training, materiel, leadership and education, personnel, facilities, policy (DOTMLPF-P) analysis and a capabilities-based assessment (CBA) to identify potential materiel and non-materiel solutions.

CHAPTER 1

INTRODUCTION

Problem Statement

In 2013, Army Special Operations Aviation (ARSOA) began to employ the MQ-1C Gray Eagle Unmanned Aircraft System (UAS), hereafter referred to as Gray Eagle, in support of special operations around the globe. Unlike the rotary wing units within ARSOA, there is not a major difference in the way that the ARSOA Gray Eagle unit is manned, trained, and equipped from that of the Conventional Force (CF) Gray Eagle units. Conversely, the rotary wing units within ARSOA have major differences in the way they are manned, trained, and equipped, in comparison to CF rotary wing units, in order to provide a unique aviation capability in support of Special Operations Aviation (SOA). Therefore, if there currently are no major differences in the way that the ARSOA Gray Eagle unit is manned, trained, and equipped, in comparison to CF Gray Eagle units, then what unique capability does the ARSOA Gray Eagle unit provide SOA? Of note, the terms manning and equipping will be used synonymously throughout this thesis with the terms organization and materiel, respectively.

Background

The concept of unmanned flight was first introduced in 1915, and by 1919 an unmanned aircraft completed a successful engagement on a captured German submarine using gyroscope-guided technology. For the Army specifically, the UAS effort began in 1953, at Fort Huachuca, Arizona, the Army's first testing and fielding location. By 1979, the Army began its first UAS acquisition program with the Aquila, which completed its operational testing in only 7 of 105 scheduled flights. This led to the Department of

1393 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Defense's first fully operational UAS program, the Pioneer, which successfully sought out SCUD missile systems and high value targets during more than 300 combat missions during Operations Desert Shield and Desert Storm. The Army continued to build its UAS capability and by the time the United States went to war in October 2001, the Army had 54 operational Hunter and Shadow unmanned aircraft in use and that number rapidly grew to over 4,000 unmanned aircraft by 2010 when the Army employed Groups 1-4 types of UAS.

Table 1. Current Systems

UAS Category	Max Gross Takeoff Weight	Normal Operating Altitude (Ft)	Airspeed	Current Army UAS in Operation
Group 1	< 20 pounds	< 1200 above ground level (AGL)	<100 Knots	RQ-11B Raven
Group 2	21-55 pounds	< 3500 AGL	<250 Knots	No current system
Group 3	< 1320 pounds	<18,000 mean sea level (MSL)		RQ-7B Shadow
Group 4	> 1320 pounds		Any Airspeed	MQ-5B, MQ-1C
Group 5		> 18,000 MSL		No current system

Source: Army UAS COE, *UAS Current Systems* (Ft. Rucker, AL. U.S. Army, 2012), 12.

The United States Army has employed the Gray Eagle for more than a decade, but it was not until 2013 that it joined the ranks of ARSOA. In 2013, Company E, 160th Special Operations Aviation Regiment (E/160) stood up as the first and only special operations aviation Gray Eagle company within the Army. Before that time Quick Reaction Capability Companies, made up of different CF UAS units, filled the SOA UAS requirements in both Iraq and Afghanistan. The formation of E/160 brought about an organic, Group 4 UAS capability to the United States Army Special Operations Command (USASOC) to support special operations forces (SOF). A holistic review of ARSOA Gray Eagle operations within SOA has not been written to capture the unique

1394 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

challenges this capability brings with it in terms of manning, training, and equipping. Currently ARSOA UAS is continuing to grow and is fielding a second Gray Eagle company (USA UAS COE 2010, 4-6). Now that the ARSOA Gray Eagle company appears to be a stable and growing capability, it is time to conduct a robust needs analysis to ensure that the unit is properly manned, trained, and equipped, from the SOF end-user perspective and not just utilizing the capabilities driven by CF requirements and analysis.

Primary Research Question

ARSOA does not employ the Gray Eagle like a CF UAS unit. However, the ARSOA Gray Eagle company is manned, trained, and equipped in almost an identical fashion as the CF UAS units. Conversely, the rotary wing ARSOA units are manned, trained, and equipped significantly different from that of rotary wing CF units. ARSOA has specific manning, training, and equipping approaches that enables its rotary wing units to have a unique capability that the CF does not have. This leads to the primary research question: are there organizational (manning), training, and materiel (equipping) capability gaps that are preventing the ARSOA Gray Eagle unit from providing a unique SOA capability? This study will illustrate whether or not the CF force development processes fully exploit the Gray Eagle's capabilities and meet SOF needs. Only by conducting a needs analysis from a SOF perspective can the force development process be reverse-engineered to ensure that ARSOA is fully exploiting the capabilities of their Gray Eagle units.

Primary Research Question

In order to answer the primary question, specific questions must be asked within the DOTMLPF-P domains of organization (manning), training, and materiel (equipping). The secondary questions to be answered in this thesis are:

1395 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

1. How does ARSOA man, train, and equip their UAS units in comparison to both CF UAS units and rotary wing ARSOA units?
2. Are there capability gaps in terms of manning, training, and equipping of the ARSOA Gray Eagle organization when compared to the rotary wing ARSOA units?
3. What are the potential materiel and non-materiel solutions to the ARSOA Gray Eagle units' domains of manning, training, and equipping, needed to provide a unique capability to SOF?

These secondary questions address specific issues under the DOTMLPF-P domains of organization, training, and materiel. Answering them will help to clearly define and focus the primary research question and this thesis.

Key Assumptions

The author makes two key assumptions in this paper. The first assumption is that the Gray Eagle and the near-term fielding of the MQ-1C Extended Range Gray Eagle UAS are the only Group 4 UAS platforms employed by ARSOA within the foreseeable future. United States Army Special Operations Aviation Command (USASOAC) has other Group 1, 2, and 3 UAS platforms, but for this study, the assumption will remain that the only Group 4 UAS employed by ARSOA is the Gray Eagle company within the 160th Special Operations Aviation Regiment (160th SOAR).

The second assumption is that the selected units used in this study represent their entire community. Specifically, this study used Company B, 3d Battalion, 82d Combat Aviation Brigade (B/3-82) to represent the CF rotary wing community; Company B, 101st Combat Aviation Brigade (B/101) to represent the CF Gray Eagle community;

1396 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Company A, 2d Battalion, 160th Special Operations Aviation Regiment (A/2-160) to represent the ARSOA rotary wing community; and Company E, 160th Special Operations Aviation Regiment (E/160) to represent the ARSOA Gray Eagle community.

Definitions and Terms

The Unmanned Aircraft System (UAS) is a complex topic, and coupled with unique aspects of the special operations community, it makes appreciation of the issues identified in this thesis challenging without an understanding of the terms presented. The key terminology in this paper will discuss; the UAS, special operations aviation, general aviation, and key terms for understanding the applied professional case study methodology.

UAS Terms

Unmanned Aircraft System (UAS): The UAS is defined as the unmanned aerial vehicle (UAV), this study will be specifically looking at the MQ-1C Gray Eagle, the ground control station (GCS), and the communications architecture (USA UAS COE 2010, 8-10). This is a key concept to understand since the UAS will commonly be referred to as a UAV, and while the UAV is a component of the overall UAS, it is not the same thing as a UAS. Unlike manned platforms, the UAS requires all the components of the system to be operational, i.e. the UAV, the GCS and the communications architecture, for the UAS to be considered operational.

Unmanned Aircraft Crewmember (UAC): UAS crewmembers will be designated in writing by their unit commander, who will specify the UAS duties and crew stations that the UACs are authorized to occupy (HQDA 2006, 13).

1397 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Unmanned Aircraft Operator (AO): The AO controls and/or monitors the actual flight of the UAS from within a GCS or similar device (HQDA 2006, 13).

Mission Payload Operator (PO): The PO is responsible for the operation of the payload sensor (HQDA 2006, 13).

Aircraft Commander (AC): The AC is responsible for control over all flight operations from pre-mission planning through debriefing. The UAS unit commander will designate aircraft commanders in writing. The AC will be responsible and have final authority for operating, servicing, and securing the UAS he or she commands, selected for each flight or series of flights, qualified and current in the UAS mission, type, design, and series (HQDA 2006, 13).

Instructor Operator (IO): The IO will train and evaluate UACs in accordance with the appropriate ATM, IOs must be designated in writing by the unit commander and be qualified and current in the UAS to be flown and must be qualified as an MC and successfully complete a Department of the Army approved IO course (HQDA 2006, 13).

Military Occupational Specialty (MOS): The grouping of duty positions requiring similar qualifications, and the performance of closely related duties (enlisted). It provides the branch, functional area, area of concentration, skill, language identification, and reporting classification used to classify the positions, and to identify individuals qualified to perform in those positions (officer) (DA PAM 611-21 2007, 12).

Additional Skill Identifier (ASI): A two-digit alpha-numeric or numeric-alpha code which identifies specialized skills that are closely related to and in addition to those required by the MOS (DA PAM 611-21 2007, 18).

Enlisted MOS 15W: Unmanned aircraft systems operator.

1398 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Remote Split Operations (RSO): Allows operators to fly UASs from stateside locations while smaller in-theater teams control takeoffs and landings. RSO has two elements: a launch and recovery element (LRE) and a mission control element (MCE). The LRE is deployed forward to launch, recover, and conduct maintenance on the UAS. The MCE remains stateside to provide command and control and provides the operators to fly the UAV while on mission.

General Aviation Terms

Pilot (PI): A rated crewmember that is qualified and current in the aircraft mission, type, design, and series (HQDA 2014c, 26).

Pilot-in-Command (PIC): A rated crewmember that is qualified, current, designated Readiness Level (RL) 1 in the aircraft mission, type, design, series, and is the individual responsible and has final authority for operating, servicing, and securing the aircraft he or she pilots (HQDA 2014c, 25).

Unit Trainer (UT): The unit commander may appoint UTs to conduct specialized training to assist in unit training programs. Rated UTs are prohibited from conducting emergency procedures training in the aircraft. UTs are also prohibited from evaluating individual, crew, and maintenance tasks (HQDA 2014c, 26).

Instructor Pilot (IP): The IP will train and evaluate aviators and other personnel in designated aircraft per the aircrew training manual (ATM). To become qualified as an IP, an aviator must be qualified as a PC and must successfully complete an approved Department of the Army instructor pilot course (HQDA 2014c, 27).

Instrument Examiner (IE): The IE will conduct instrument training and instrument flight evaluations per the ATM. To become qualified as an IE, an aviator must be an IP in

1399 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

either aircraft category, and successfully complete a Department of the Army approved course of instruction for IEs (HQDA 2014c, 27).

Readiness Levels (RLs): Aviation commanders use a series of RLs to develop individual and crew proficiencies that support collective tasks. RLs identify the training phase in which aircrew members (ACM) are participating and measure ACM readiness (HQDA 2016a, 51).

Mission Approval Process: The mission approval process for aviation operations is accomplished in three steps that must be completed prior to mission execution. The three steps are: initial mission approval, mission briefing and planning, and final mission approval authority (HQDA 2014c, 9).

Initial Mission Approval: Commanders or their designated representatives (operations officer, S–3, and so forth) determine the mission feasibility and either accept or reject the mission for the command (HQDA 2014c, 9).

Mission Briefing Officer (MBO): The MBO is the Commander or his/her designated representative that interacts with the mission crew or air mission commander to identify, assess, and mitigate risk for the specific mission. Commanders will select MBOs based on their experience, maturity, judgment, and ability to effectively mitigate risk to the aircrew and designates them by name and in writing (HQDA 2014c, 9).

Final Mission Approval Authority (FMAA/MAA): Members of the chain of command who are responsible for accepting risk and approving all aviation operations (ground and air) within their unit. They approve missions for a specific risk level. FMAAs may only approve those missions whose assessed risk level is commensurate with their command level (HQDA 2014c, 9).

1400 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Instrument Flight Rules (IFR): Instrument meteorological conditions is an aviation flight category that describes weather conditions that require pilots to fly primarily by reference to instruments, and therefore under instrument flight rules (IFR), rather than by outside visual references under visual flight rules.

Special Operations Aviation Terms

Army Special Operations Aviation (ARSOA): Designated active component forces and units organized, trained, and equipped specifically to conduct air mobility, close combat attack, and other special air operations (ADRP 3-05 2012, 47). Additionally, it is important to understand that Special Operations Aviation (SOA) supports other special operations forces units by planning and conducting special air operations in all operational environments. These specially organized, trained, and equipped aviation units provide the joint force special operations component commander with the capability to infiltrate, resupply, and exfiltrate SOF elements engaged in all special operations core activities (ADRP 3-05 2012, 47).

Battle-Rostering: Battle-rostering is defined as the designation of two or more individuals to routinely perform as a crew (HQDA 2013a, 12-13).

ARSOA Battle-Rostering: In addition to the practice of battle-rostering, individual crew members and SOA crews are further organized based on the level of mission qualification they have achieved. This modification to the aircrew model can be applied across the spectrum of SOA missions, in both training and combat, and provides the commander a clear tool to control risk while retaining mission flexibility and ensuring successful support of the ground force commander's intent (HQDA 2013a, 12-13).

1401 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Basic Mission Qualified (BMQ): BMQ pilots may perform PC or pilot (PI) duties during internal training or perform PI duties on internal/external training (HQDA 2013a, 14-15).

Fully Mission Qualified (FMQ): FMQ pilots may perform PC or PI duties during the conduct of internal and external training; they may also formally train for Flight Lead (FL) during internal training (HQDA 2013a, 14-15).

Flight Lead Qualified (FLQ/FLD): FLQ pilots may perform FL, PC, or PI duties on any internal or external training as assigned. The FLQ is primarily responsible for the planning and execution of SOA missions (HQDA 2013a, 14-15).

Applied Professional Case Study Methodology Terms

The following professional terms are part of the applied professional case study methodology. They are used by the process operators in the force development community to describe the system utilized for developing capabilities routinely and are used in the methodology of this study.

Joint Capabilities Integration and Development System (JCIDS): The JCIDS is one of DOD's three primary decision support processes for shaping the military forces to support strategic guidance documents. JCIDS is a capabilities-based approach to identify current and future capability gaps in the joint force ability to carry out joint warfighting missions and functions. The objective of JCIDS is to develop a balanced and synchronized Doctrine, Organization, Training, Materiel, Leadership and Education, Personnel, Facilities, and Policy (DOTMLPF-P) solution (F102RA 2017, 2).

Doctrine, Organization, Training, Materiel, Leadership and Education, Personnel, Facilities, and Policy (DOTMLPF-P): This is the process used to develop change

1402 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

recommendations on how to optimize the joint force's ability to operate as an integrated force. The deliberate process is characterized by the traditional route to identifying capability gaps and proposed solutions, through the use of the capabilities-based assessment process (F102RA 2017, 2).

Capabilities-Based Assessment (CBA): An analytic basis to identify capability requirements and associated capability gaps, as part of a process that produces an integrated set of DOTMLPF-P solution approaches that collectively provide the required capabilities (F102RA 2017, 3).

Functional Area Analysis (FAA): The first analytical phase of the CBA and is strictly a capabilities-based task analysis. The FAA provides the framework to assess required capabilities in the follow-on Functional Needs Assessment (FNA). The FAA is based on professional military knowledge of established doctrine and standards that are modified to account for the projected concept for future operations and organizations (F102RA 2017, 21).

Functional Needs Assessment (FNA): This is the second analytic phase in the CBA. It assesses the ability of current and programmed Army capabilities to accomplish the tasks identified in the FAA and identifies any gaps and overlaps in capabilities and the risk posed by those gaps (F102RA 2017, 22).

Functional Solutions Analysis (FSA): The FSA is the third analytic phase in the CBA. It is an operationally based assessment of potential non-materiel DOTMLPF-P and/or materiel approaches to solving or mitigating one or more of the capability needs determined from the FNA. The FSA describes the ability of each identified approach to satisfy the need. Approaches proposed by an FSA must meet three criteria: first, they

1403 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

must be strategically responsive and deliver approaches when and where they are needed; second, they must be feasible with respect to policy, sustainment, personnel limitations, and technological risk; and third, they must be attainable, in that DOD could actually resource and implement the approaches within the timeframe required (F102RA 2017, 22).

The Kotter Change Model: An eight-step process used for leading change within an organization. The model provides a foundational approach, with each stage building upon the success of the previous stage. The first four stages assist in overcoming the existing status quo and set the conditions for leading change. Stages five through seven are the action stages that move the change effort from words to action by introducing new or different practices into the organization. Without successfully completing these three action stages the effort loses momentum, the sense of urgency dissipates, and the coalition becomes marginalized. Kotter's final stage, stage eight, is reached when the changes are inculcated into the culture of the organization; the change becomes the status quo and accepted within the organization (Miller and Turner 2017, 1-3).

Modification Table of Organization and Equipment (MTOE): A table which prescribes in a single document the modification of a basic table of organization and equipment necessary to adapt it to the needs of a specific unit or type of unit (DA PAM 611-21 2007, 14).

Limitations and Delimitations

The most significant limitation of this study will be the inability to publish classified data regarding the ARSOA Gray Eagle unit of study in this thesis. The study may not clearly depict the employment of this unit without being able to annotate its

1404 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

locations around the globe and effects on the battlefield. Specifically, the study will not assess the unit's current deployed locations or operations within those areas due to classification. This is significant, as one major premise of this paper is to accurately illustrate why the ARSOA UAS unit needs to be manned, trained and equipped differently than the CF to provide a unique capability within SOA. Additionally, the study will identify capability gaps and potential materiel and non-materiel solutions to ensure the Gray Eagle provides SOA with a unique UAS capability. Specific DOTMLPF-P domains that will be addressed are the organization, training, and materiel of the unit as it is currently being employed, which will be difficult to articulate without describing the unit's current and past employment due to classification. However, this study will look at all available unclassified sources pertaining to the primary and secondary research questions.

The next limitation is that there is no research, with regards to specific literature, that addresses the employment of the ARSOA Gray Eagle unit, in relation to UAS employment by the CF. This gives no predictive notion to address going into this study. This is significant, as there is no baseline to determine whether or not changes must be made to the unit's manning, training, and equipping to ensure continued success within the special operations community. To mitigate this limitation, the methodology being used will objectively look at the aspects surrounding this gap in literature, to present a non-biased solution to the key stakeholders. The study will also illustrate that a SOF-specific needs analysis must be conducted so that ARSOA Gray Eagle units are not vulnerable to changes in the CF's force development process and to define what future changes might mean for readiness and training.

1405 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Another delimitation for this study is that it will only consider the employment of the ARSOA Gray Eagle as beginning with the creation of E/160 in 2013. The study will not include the employment of the Gray Eagle within special operations during the operations of the Quick Reaction Capability Companies, when they supported special operations forces in Iraq and Afghanistan prior to the creation of E/160.

The last delimitation is that in order to illustrate the difference between ARSOA and CF rotary wing capabilities, this study will only look at the difference between the similar ARSOA multi-mission rotary wing, MH-47, and the CF cargo rotary wing, CH-47 units. This comparison will be used to identify any gaps in the manning, training, and equipping of ARSOA Gray Eagle and the CF Gray Eagle units, in comparison to ARSOA and CF rotary wing units. This delimitation will not take away from the credibility of this study as the only other similar units between ARSOA and the CF would be between the ARSOA multi-mission rotary wing, MH-60, and the CF utility rotary wing, UH-60 units.

Significance of Study

The results of this study will identify any capability gaps in the manning, training, and equipping of the ARSOA Gray Eagle unit that may prevent it from providing a unique UAS SOA capability. This will be based on a comparative analysis of the CF Gray Eagle unit, by comparing the similarities and differences between the ARSOA and CF Gray Eagle units. The study will then look to the ARSOA rotary wing units for potential materiel and non-materiel solutions by analyzing the differences in the ARSOA rotary wing units from those of the CF rotary wing units. This is significant because it will not only identify the domains in which capability gaps exist, but will also look to an established SOA unit for potential solutions.

1406 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

R1: Initial Personal Recommendation

The applied professional case study is a research methodology that incorporates three different assessments throughout the process, R1, R2, and R3. The initial assessment, or R1, is the author's perspective, bias, and assumptions prior to beginning the review of literature. This initial assessment provides a starting point to the research and gives it credibility throughout the rest of the process.

The first part of the R1 discusses the primary research question and why it is important to the author and the key stakeholders within USASOC. The primary research question in this study is: are there organizational, training, and materiel capability gaps that are preventing the ARSOA Gray Eagle unit from providing a unique SOA capability? The author developed this research question after spending approximately 18 months in the only ARSOA Gray Eagle company, E/160, as the executive officer just prior to beginning this study. In addition to those 18 months in E/160, the author spent over 5 years in the 160th SOAR, primarily within the rotary wing units. This experience gave the author an understanding of the Gray Eagle, its role within the 160th SOAR, and the Soldiers who operate and maintain the Gray Eagle. With that understanding, the author believes there are capability gaps that must be addressed for this platform to perform at the same level as the rotary wing units within the 160th SOAR. The author has a vested interest in this study because he will be returning to the 160th SOAR after this study to work with E/160 and believes that it must begin to mirror the ARSOA rotary wing units in terms of manning, training, and equipping, to provide a unique SOA UAS capability to the special operations community.

This study is important because if E/160 is expected to provide the same unique capabilities as the rotary wing units within the 160th SOAR, then the key stakeholders

1407 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

need to look at the capability gaps that E/160 has in terms of manning, training, and equipping when compared to the rotary wing units in the 160th SOAR. The Gray Eagle is still within its first five years of employment within ARSOA, and the earlier that these capability gaps can be identified and addressed, the easier it will be to define the unique UAS capability that E/160 brings to the special operations community. Additionally, a second Gray Eagle company is currently being fielded with an August 2018 activation date. Any changes to the organization, training, and materiel of this new company will be less intrusive if identified and implemented early during the standing up of this new company.

The second part of the R1 addresses why this study is important and the possible consequences if this topic is not addressed. The demand for combat air patrols provided by ARSOA Gray Eagle is going to increase, as evidenced by the fielding of a second Gray Eagle company within the 160th SOAR. Additionally, the Department of Defense (DOD) is continuing to invest in the advancement of the Gray Eagle with the production of the Extended Range (ER) Gray Eagle, which is scheduled to undergo initial operational testing and evaluation (IOT&E) by ARSOA in fiscal year 2018 (FY18). The United States Special Operations Command (USSOCOM) is investing in the advancement of a unique SOA UAS capability and identifying the capability gaps in terms of organization, training, and materiel will ensure that these investments are made to the most critical capability gaps identified in this study. If this analysis is not done and investment is made in areas that do not truly increase the capability provided, the consequence will be that USSOCOM used constrained fiscal resources without equitable payoff.

1408 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The final portion of the R1 identifies the potential for a solution to the problem statement, the methodology by which it could be answered, and the author's initial recommended solutions. The author believes that there are potential solutions to the problem statement and that looking to the ARSOA rotary wing units for these solutions should be the starting point. The 160th SOAR has had 36 years to develop and implement unique SOA capabilities. This is in line with the SOF truth that special operations capabilities cannot be mass produced. E/160 is reaching its 5th year of conducting operations as part of the 160th SOAR and the unit needs to start establishing unique SOA UAS capabilities to support special operations with abilities not offered by CF UAS units. Informing key stakeholders of these potential solutions, with a rich description of the environment, will persuade them to make key changes that will ensure this capability is poised to support the unique requirements of special operations.

This problem will require the methodology to use the correct data to determine possible solutions. To determine the potential capability gaps in E/160's manning, training, and equipping, this study will need to look at data that accurately depicts E/160's current organization structure, training process, and equipping. Additionally, this study will look at this same data from ARSOA rotary wing units, CF rotary wing units, and CF Gray Eagle units. After gathering the right data, an applied professional case study will be used,

> Case studies are a useful method for conducting qualitative research for problem areas that are human-centric, dynamic, volatile, and contain a mix of stakeholders, interests, variables and information concepts that demand a deep understanding of context in order to produce informed policy choices" (Creswell, 2009, 2013, 2014; Yin, 2014).

The study will then use a comparative analysis from the data gathered through the case study and use a modified DOTMLPF-P Capabilities Based Assessment (CBA) to

1409 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

determine the results. A CBA is appropriate since it is a structured three phased process that identifies and documents capability gaps; determines the attributes of a capability or combination of capabilities that would resolve the gaps; and identifies non-materiel as well as materiel approaches for possible solutions. By conducting the applied professional case study and then analyzing it using the CBA, we get the functional solution analysis (FSA). This will identify a resolution, and will look to potential DOTMLPF-P approaches, recommendations, and solutions to mitigate or eliminate the capability gaps and will produce suggestions to implement ideas for non-materiel DOTMLPF-P approaches; and ideas for materiel approaches.

Conclusion

Since its inception in 2013, the ARSOA Gray Eagle unit has enabled special operations across the globe with phenomenal results. This success brought an increased demand within ARSOA which led to the current fielding of another MQ-1C Gray Eagle company within ARSOA. This chapter discussed the background, the problem, and the process by which this study will be conducted. The next chapter will analyze the literature used for this study.

1410 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CHAPTER 2

LITERATURE REVIEW

Introduction

The purpose of this research is to gain a rich understanding of the unique capabilities required by the ARSOA Gray Eagle unit to meet special operations specific requirements, and to persuade the Chief Decision Maker (CDM) and key stakeholders to affect change. The literature is primarily from the Department of Defense (DOD) and other federal agencies because the purpose of this study is to persuade key stakeholders within the DOD. By primarily using the professional body of knowledge, it tailors the information and makes it credible to the target audience. This remains in line with the research methodology as a professional applied case study.

The specific areas that will be addressed in this chapter are the manning, training, and equipping of the unit and whether it is specifically designed to support special operations in the same manner as the rotary wing ARSOA units.

Key Literature

The following graph depicts the literature reviewed in this study and how each piece of literature specifically applies to the different aspects of this paper.

The *United States Army Roadmap for UAS 2010-2035* is the Army's vision to develop, organize, employ, and build a comprehensive strategy for defining future UAS requirements. This publication breaks down this strategy into the time periods of near (2010-2015), mid (2016-2025), and far (2026-2035). Through these different time frames, the document focuses on issues such as identifying current gaps in capabilities, integrating UAS into other Army operations such as networking and cargo capabilities, and increasing the overall capability of the UAS while reducing its size, power, and weight requirements. This roadmap is reviewed every two years, but a new edition has

1412 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

not been published since this initial document. While the document is over seven years out of date, it still provides a good assessment as to whether or not the Army is on the right track to meet its intended goals.

This reference applies to this study as it addresses both the primary and secondary research questions of this thesis. Specifically, it describes the UAS in terms of manning, training, and equipping, and it breaks down the assessment into the DOTMLPF-P domains, which falls directly in line with the methodology used in this study. Additionally, this document discusses the challenges with UAS operations within the NAS and addresses many other issues with the employment of the UAS, which may fall outside the scope of this study, but are still necessary to consider.

The *Unmanned Systems Integrated Roadmap FY2013-2038* is a document intended to "articulate a vision and strategy for the continued development, production, test, training, operation, and sustainment of unmanned systems technology across DoD." It looks at both current and future capabilities in a 25-year window to address where UAS is now, and to develop a strategy to determine where it should go. While this document does not specifically address special operations, it does identify with many of the same gaps in capabilities that could be used within special operations as well as with CFs. Additionally, it addresses the manning, training, and equipping aspects of this thesis.

Much like the *United States Army Roadmap for UAS 2010-2035*, this document discusses UAS operations in terms of near, mid, and far time frames. Unlike the *United States Army Roadmap for UAS 2010-2035*, this publication is not solely focused on the Army UAS program but on the Department of Defense as a whole, which gives this document a more strategic aim. Specifically, the *Unmanned Systems Integrated Roadmap*

1413 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

FY 2013-2038 discusses strategic planning and policy, combatant commander mission and capability needs, technologies for unmanned systems, operating environment, sustainment and logistics, training, and international cooperation.

Of the topics discussed in this thesis, *The Unmanned Systems Integrated Roadmap FY 2013-2038* addresses the equipping aspect in the most detail. For example, it addresses several types of munitions that could improve the capabilities of the MQ-1C Gray Eagle aerial vehicle. One of which is the Direct Attack Guided Rocket (DAGR). The DAGR is a 2.75-inch laser guided rocket that is fully compatible with the current Hellfire system. This new munition would potentially allow the MQ-1C Gray Eagle to carry up to four times as much payload as its current configuration. Additionally, this document extensively describes the communications architecture and potential use of existing networks, specifically the Defense Information Systems Network (DISN) and the teleport standard tactical entry point (STEP) sites. The ability to plug into these global networks and gain access to satellite coverage around the globe would provide an increased capability for ARSOA UAS in terms of its operational reach. *The Unmanned Systems Integrated Roadmap FY 2013-2038* provides a great deal of information from very specific aircraft-defining characteristics to broad strategic level policy. It provides insight to many of the topics discussed in this thesis and other aspects within the UAS community.

The *MQ-1C Gray Eagle Selected Acquisition Report (SAR),* as of the FY2017 President's budget, discusses several topics relevant to this study. First, it discusses the proposed employment design of Gray Eagle units in terms of organization. Specifically, it addresses how the unit is intended to operate and why it is organized the way that it is. In

1414 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

support of United States Army Divisions, the UAS company is part of the combat aviation brigade (CAB); in support of Intelligence Command (INSCOM), it is part of the 116th Military Intelligence Brigade, and in support of USASOC it is part of the 160th SOAR. Within each of these organizations, the UAS company is broken down into three identical platoons, giving the commander extreme flexibility to employ this asset. This document explains that the intent of the UAS company's structure from inception was for each platoon to be able to operate independently at three geographically dispersed locations.

The Chairman of the Joint Chiefs of Staff Instruction (CJCSI) 3255.01- Joint Unmanned Aircraft System Minimum Training Standards document provides the basis for joint unmanned aircraft system minimum training standards and identifies the training requirements for UAS crewmembers to operate in support of a joint force commander. It breaks the requirements down into three categories: Basic UAS Qualification (possessing the general aviation and UAS knowledge to safely operate a UAS), possessing the skills required to both operate the UAS and maintain situational awareness to execute tasks, and Joint Mission Qualification (understanding the UAS mission/objective and its role in accomplishing the larger military operation). This document directly applies to this thesis as it is essentially a contract between the Department of Defense and the FAA, establishing the minimum training requirements that a UAS operator must possess to operate in the NAS.

The *TC 3-04.63 MQ–1C Unmanned Aircraft System Commander's Aircrew Training Program and Aircrew Training Manual* applies to Gray Eagle crewmembers and their commanders. The purpose of this document is to standardize aircrew training

1415 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

programs and flight evaluation procedures by providing specific guidelines for executing UAS aircrew training. This training circular outlines both the individual and collective training requirements for crewmembers in order to advise the commander on an effective aircrew training program that supports combined arms training. Of note, the *MQ–1C Unmanned Aircraft System Commander's Aircrew Training Program and Aircrew Training Manual* is combined into one document to cover both the Gray Eagle specific aircrew training program and the commander's aircrew training program for individual, crew, and collective training. While the Commander's Aviation Training and Standardization Program incorporates the UAS, it admittedly states that the UAS integration is still developing and needs refinement, which makes the *MQ–1C Unmanned Aircraft System Commander's Aircrew Training Program and Aircrew Training Manual* publication the most relevant document to Gray Eagle operations. This is significant because this study will examine the corresponding CF and ARSOA rotary wing publications as part of the analysis for this thesis. For those elements, there are two distinct publications, an airframe specific aircrew training manual and a general aviation commander's aircrew training program for individual, crew, and collective training. Additionally, it is important to note that the CF and ARSOA Gray Eagle units both use this same document.

The aircrew training program outlined in this publication applies to crewmembers that perform duties controlling the flight of a UAV or the operation of its mission equipment. This includes starting the engine, takeoff and/or landing the UAV and consists of qualification, refresher, mission, and continuation training. It outlines the requirements for qualification in the Gray Eagle, criteria for readiness level progression,

1416 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

flight activity category designation, flight hour/currency requirements and annual task and iteration requirements. This publication also outlines the testing and evaluating requirements for crewmembers during a proficiency flight evaluation, annual proficiency and readiness evaluation, and other crewmember proficiency based testing.

In summary, this document contains the necessary guidance for a Gray Eagle company commander to execute the aircrew training program that covers everything from individual to collective unit training. Additionally, this document is the aircrew training manual for the Gray Eagle and is the basis for the crewmember's training from the individual to collective training levels.

The *TC 3-04.11 Commander's Aviation Training and Standardization Program* is the commander's guidance for implementing a standardized aviation training program. It applies to all individuals flying Army aircraft and for the purposes of this study, it directly applies to CH-47F and Gray Eagle crewmembers. It does not apply to ARSOA MH-47G crewmembers, as ARSOA has its own publication for the execution of the commander's aircrew training program.

This publication focuses on the implementation of an effective, standardized aircrew training program that supports the mission of the combat aviation brigade. It outlines the individual responsibilities in executing the training program from the brigade commander down to the individual crewmember. Like the aircrew training manuals, it addresses individual qualification, currency, and flight hour requirements, but these are not the focus. In contrast to an aircrew training manual, the focus of this document is to serve as a guideline to all Army aircraft as a holistic approach to Army aviation training and standardization. For example, it specifically addresses aircrew training plan

1417 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

management, doctrinal training concepts, unit collective training requirements, and the implementation of the Army standardization program.

The *ARSOA TC 3-04.11 Commander's Aircrew Training Program for Individual, Crew, and Collective Training* is the keystone publication that establishes the requirements for commanders at all levels to develop, manage, and administer a comprehensive aircrew training program. In the context of this study, this publication applies directly to the ARSOA MH-47G crewmembers, but does not address ARSOA Gray Eagle crewmembers.

This reference covers much of the same material as the *TC 3-04.11 Commander's Aviation Training and Standardization Program*, but applies only to ARSOA crewmembers. This publication addresses the responsibilities of the 160th SOAR Commander down to the individual crewmember, aircrew training program administration, risk management, training and evaluation requirements, and standardization for aviation records. The most important element of this publication, with regards to this study, is that it addresses how ARSOA battle rosters their crews in terms of PI, PC, BMQ, FMQ, and FLD designations. This is an important distinction as the *TC 3-04.11 Commander's Aviation Training and Standardization Program* also addresses crew battle rostering but only in terms of PI/AO and PC/AC designations. This distinction will be addressed in chapter four, but it is important to note that while the ARSOA MH-47G crewmembers have additional crewmember designations of BMQ, FMQ, and FLD, the ARSOA Gray Eagle crewmembers only have the designations of AO and AC. *The ARSOA TC 3-04.11 Commander's Aircrew Training Program for Individual Crew, and Collective Training* specifies the type of crew mix (PI, PC, BMQ, FMQ, FLD)

1418 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

required for different mission sets (internal training, external training, administrative support, and tactical).

The *TC 3-04.34 Aircrew Training Manual, Cargo Rotary wing, CH-47D/F* applies to all CH-47 crewmembers and their commanders in the active Army, the Army National Guard Bureau/United States Army National Guard, the United States Army Reserve, and provides specific guidelines for executing CH-47D/F aircrew training. This publication is the basis for crewmember qualification training, refresher training, mission training, and continuation training and evaluation requirements.

This reference is used in conjunction with the *TC 3-04.11 Commander's Aviation Training and Standardization Program* publication to help commanders and crewmembers execute the aviation training program. The main difference is that the *TC 3-04.34 Aircrew Training Manual, Cargo Rotary wing, CH-47D/F*, provides the performance standards and evaluation guidelines for every individual/mission/collective task, so that crewmembers know the level of performance expected. It is the primary tool used by commanders and standardization officers to implement the aircrew training program. This manual is intended to support the unit's mission essential task list by enhancing training in individual and aircrew proficiency.

The *ARSOA Aircrew Training Program Aircrew Training Manual Multi-Mission Rotary wing MH-47*, much like the *TC 3-04.34 Aircrew Training Manual, Cargo Rotary wing, CH-47D/F*, is the basis for crewmember qualification training, refresher training, mission training, and continuation training and evaluation requirements. It applies to all MH-47 crewmembers, their commanders, and standardization officers. It is used in conjunction with the *ARSOA TC 3-04.11 Commander's Aircrew Training Program for*

1419 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Individual Crew, and Collective Training and other applicable publications to aid both the individual and commander in developing an effective and standardized aircrew training program for the unit. It establishes the task, conditions, and standards for all individual and collective tasks for employment of the MH-47 aircraft. Specific to this study, the *ARSOA TC 3-04.11 Commander's Aircrew Training Program for Individual Crew, and Collective Training* outlines specific special operations aviation tasks that are not listed in the CF *TC 3-04.34 Aircrew Training Manual, Cargo Rotary wing, CH-47D/F*. These tasks provide additional capabilities to the special operations community that the CF cargo rotary wing, CH-47D/F, units cannot provide.

After reviewing the applicable aircrew training documents for the ARSOA and CF units used in this study, the following discussion on aircrew training progression and crewmember designations is necessary to understand the results of this study described in chapter four. This discussion will begin with describing the aircrew training program, which is almost identical for manned and unmanned airframes, and will conclude with aircrew member designations that distinguish the ARSOA process from the CF process, and is a key point to understand for this study.

Readiness levels (RLs) are used by aviation commanders to determine the proficiency of crewmembers in their base, mission, and additional tasks. RLs are designated progression points that range from RL1 to RL3, with RL3 being the designation for a crewmember focusing on base tasks, to a mission ready crewmember with an RL1 designation (HQDA 2016a, 51). Base tasks, or 1000 series tasks, are made up of individual tasks or maneuvers that a crewmember is expected to be able to perform, both in and out of the airframe. An example of a base task for a CH-47F rated

1420 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

crewmember would be to perform hovering flight, task #1038 (HQDA 2013b, 101). Once the crewmember demonstrates proficiency in all base tasks listed in that airframes applicable aircrew training manual, they are designated RL2. During RL2 training, the crewmember must demonstrate proficiency in all mission and additional tasks (or 2000 series and 3000 series tasks, respectively) that support the unit's mission essential task list, as assigned by that crewmember's aircrew training program commander. An example of a mission task for a Gray Eagle operator would be to operate synthetic aperture radar, task #2305 (HQDA 2014b, 200). Once a crewmember completes all RL2 training requirements, they are designated RL1.

Once a crewmember is designated RL1, they continue their flight training through continuation training which has different requirements based on that crewmembers Flight Activity Category (FAC). FAC levels are designated by the brigade level commander and are based on flight task requirements and the proficiency required by the individual crewmember's MTOE or TDA position. FAC levels are broken down into FAC 1 through FAC 3. A FAC 1 position requires a high degree of proficiency in the tactical employment of the assigned airframe. A FAC 2 position requires the same proficiency in individual and crew tasks as a FAC 1 position but does not necessarily require the same collective proficiency in unit tasks. FAC 3 positions are not authorized to perform crewmember duties in their assigned airframes but must complete applicable simulator hour requirements, if a compatible simulator is available. Each FAC level has a corresponding semi-annual flight hour requirement, that is considered the continuation training as previously discussed (HQDA 2016a, 66-67). For example, an RL1, FAC 1, MH-47G rated crewmember has a semi-annual flight hour requirement of 60 hours, 30 of

1421 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

which must be completed using night vision goggles. An RL1, FAC 2, MH-47G rated crewmember has a semi-annual flight hour requirement of 33 hours, 18 of which must be completed using night vision goggles (HQDA 2013a, 47; ATM 2014, 19). In addition to semi-annual flight hour requirements, crewmembers have an annual requirement to complete an annual proficiency and readiness test (APART). The APART is conducted each year during a crewmember's APART window which is based on their birth month. The APART is slightly different for each airframe, but it essentially consists of a hands-on evaluation, a written evaluation, and a flight physical (DD Form 2992, Medical Recommendation for Flying Duty) (HQDA 2016a, 71).

Crewmembers have an obligation to complete applicable RL progression and continuation training but are also required to progress in their crewmember designation. In the Gray Eagle community, UAS crewmembers (UACs) have the following designations; unmanned aircraft operator (AO), mission payload operator, (PO), aircraft commander (AC), unit trainer (UT), instructor operator (IO), standardization instructor operator (SO), and mission commander (MC). Upon successful completion of a Department of the Army approved Gray Eagle qualification course and designation in writing from the aircrew training program commander, UACs begin their aviation careers with the designation as an AO, and a PO.

An AO is responsible to control the flight of an UAS or the operation of its mission equipment and remain tactically and technically proficient as an UAC. The individual operator should have the ultimate goal of achieving AC status (HQDA 2016a, 51). An AC has the same requirements as an AO, but additionally they are responsible for the overall safety of the UAV, be proficient in the UAV and all aspects of the unit

1422 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

mission essential task list, the conduct of all operational and training aspects of a specific mission, all actions of the crew, assigning duties to the crew, and for accomplishing the assigned missions.

From there, the UAC looks to progress to a UT, who has all the responsibilities of an AC but is additionally responsible to instruct in appropriate tasks and subjects, recognize errors in performance or understanding, make recommendations for improvement, train to standards, and document training (HQDA 2014b, 24-32). After designation as a UT, and with input and concurrence of the command level leadership, a UT will attend an approved Department of the Army Gray Eagle Instructor Operator (IO) course to undergo training. Of note, a UAC does not have to be designated as a UT to be sent to the IO course, this just represents a normal progression for a UAC from initial assignment to designation as an IO.

After successful completion of the IO course and designation in writing from the aircrew training program commander, that UAC is designated as an IO. The IO has all the requirements of a UT and is the unit's primary trainer and evaluator of all UACs. The SO is the final aircrew designation for a UAC. Normally, an IO will train for multiple years before being recommended by the command to be designated as an SO. After designation in writing by an aircrew training program commander, an IO is authorized to perform SO duties. An SO has all the responsibilities of an IO and primarily trains and evaluates the unit's IO. Additionally, an SO is the primary advisor to the commander on all aspects of the unit's aircrew training program (HQDA 2006, 14).

The CH-47F and MH-47G rated aviators used in this study have the following aircrew designations; Pilot (PI), Pilot in Command (PC), Unit Trainer (UT), Instructor

1423 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Pilot (IP), Instrument Examiner or Instrument Flight Examiner (IE or IFE), and Standardization Instructor Pilot (SP). Of note, rated aviators have other aircrew designations, but those are not applicable for the purposes of this study (HQDA 2014c, 27).

Upon successful completion of a Department of an Army approved qualification course, and designation in writing by the ATP commander, new rated aviators begin their aviation career with the designation as a PI. A PI has the responsibility to remain tactically and technically proficient in all aircrew member tasks as dictated by the applicable aircraft training manual. PIs should take advantage of every training opportunity with the goal of attaining designation as a PC.

After demonstrating proficiency in all required aircraft tasks, successfully completing a PC evaluation in accordance with applicable publications, displaying proper judgement and maturity, and being designated in writing by the ATP commander, a rated aviator is then designated as a PC. A PC has all the responsibilities as a PI, but is additionally responsible to ensure the overall safe and effective operation of the aircraft, to serve as the unit's first-level trainer, be proficient in the aircraft and all aspects of the unit's collective tasks. The PC is responsible for the safety of all occupants, and the conduct of all operational and training aspects of a specific mission, responsible for all actions of the crew, responsible for assigning duties to the crew, and responsible for accomplishing assigned missions (HQDA 2014c, 26).

At this point in the aircrew progression process, it is important to note several significant differences between rotary wing pilots and UAS operators. First, the Army's rotary wing pilots are primarily warrant officers and the Army's UAS operators are

1424 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

primarily enlisted soldiers and non-commissioned officers. To be clear, there are also commissioned officers that are rated aviators and there are warrant officers that are UAS operators, but for the purposes of this study, they are not included in the discussion. The next significant difference is that warrant officers track different career paths during their professional careers. Unlike UAS operators, a warrant officer's progression to IP is dependent upon the career path they decide to track. For example, a warrant officer may decide that they would like to track safety to become an aviation safety officer and because of that, they would never achieve an aircrew designation as an IP. There are a few warrant officers that track multiple career paths, but it is not the norm. In contrast, UAS operators do not have multiple career track options like warrant officers and because of this each UAS operator should strive to progress to IO.

For comparison in this study, a warrant officer who decides to career track IP would look to progress to the designation of a UT after achieving PC status. A UT has the same responsibilities as a PC; but in addition, a UT has demonstrated the ability to train other pilots and focuses primarily on RL 2 and RL 1 progression training. At some point in the warrant officer's career and service as a UT, they will attend a Department of the Army instructor pilot qualification course resulting in designation as a unit IP by the ATP commander. IPs have the same responsibilities as a PC, but in addition, they serve as the primary instructors and evaluators for the unit. Normally after a few years as an IP, the command will determine whether or not to give an IP an SP evaluation based on their performance as an IP. After successfully completing an SP evaluation in accordance with applicable publications and a designation in writing by the ATP commander, an IP is designated as an SP. An SP has all the responsibilities of an IP but SPs are also primarily

1425 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

responsible for the training and evaluation of IPs, and serve as the primary advisor to the commander on all matters pertaining to the unit's ATP.

The final aircrew designation for this study is the designation as an IE or IFE. There is not a correlating designation within the UAS community but it is still relevant for the purpose of this study. The reason is that the Gray Eagle is not rated for IFR flight, and because of that, there is no need to designate UACs as IEs. To be designated as an IE, an aircrew member must already be designated as an IP and successfully complete a Department of the Army approved IE qualification course and be designated in writing by the ATP commander. An IE has the primary responsibility to administer instrument flight evaluations within the unit. The designation as an IE is not airframe specific like the other aircrew designations; for example, an IE whose primary aircraft is a CH-47 can give an instrument evaluation to an aviator whose primary aircraft is a UH-60 (HQDA 2014c, 27).

An understanding of the aircrew member training, progression, and aircrew designation processes of both the manned and unmanned platforms discussed in this study is essential to gain an understanding of the unique ARSOA mission qualification and battle-rostering process discussed in the next section.

ARSOA rotary wing units use a unique battle-rostering process that is based on mission qualification. This process is unique to ARSOA and is not used by CFs rotary wing units, B/101, or by E/160, that is key to note for the purposes of this study. The intent of this unique battle-rostering process is to ensure successful accomplishment with the minimum amount of risk to the force and to the SOA mission. ARSOA has the following mission qualification designations; basic mission qualified (BMQ), fully

1426 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

mission qualified (FMQ), and flight lead qualified (FLD). Once a rated crewmember successfully completes the special operations basic mission qualification course conducted by the 160th Special Operations Aviation Training Battalion, that crewmember is designated as an RL 1, PI, BMQ, and assigned to an operational company within the 160th SOAR. The rated crewmember then conducts mission training with the goal of achieving FMQ designation. After extensive training and successful completion of an FMQ evaluation and designation in writing by the ATP commander, that crewmember is designated as an FMQ. The final mission qualification is that of FLD. Significant to this study, the FLD qualification usually takes many years to achieve, and is a designation that not every rated crewmember in the 160th SOAR will achieve. It illustrates mastery of all SOA required mission sets and the highest degree of tactical and technical proficiency. After many years of extensive training, successful completion of a FLD evaluation, and designation in writing by the 160th SOAR Commander, that crewmember is designated as a FLD. These mission qualifications are used to determine the right battle-rostering based on mission requirements.

The *Technical Manual Operator's Manual for the MH-47G, TM 1-1520-272-10-1* provides complete operating instructions and procedures for the multi-mission rotary wing, MH-47G. Specifically, it covers aircraft and systems description and operation, avionics, mission equipment, operating limits and restrictions, weight/balance and loading, performance data, normal procedures, and emergency procedures for the MH-47G.

The *Operator's Manual for the CH-47F, TM 1-1520-271-10-1* provides complete operating instructions and procedures for the cargo rotary wing, CH-47F. Specifically, it

1427 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

covers aircraft and systems description and operation, avionics, mission equipment, operating limits and restrictions, weight/balance and loading, performance data, normal procedures, and emergency procedures for the CH-47F.

The *Operator's Manual for the MQ-1C Unmanned Aircraft System, TM DTM 1-1550-697-10-1*, provides complete operating instructions and procedures for the unmanned aircraft system, MQ-1C. Specifically, it covers aircraft and systems description and operation, avionics, mission equipment, operating limits and restrictions, weight/balance and loading, performance data, normal procedures, and emergency procedures for the MQ-1C.

The *Unmanned Aircraft System Flight Regulations, AR 95-23*, much like the *TC 3-04.11 Commander's Aviation Training and Standardization Program*, provides guidance on UAS crewmember training, risk management, currency requirements, training and standardization. In addition, this regulation also covers flight rules, UAS general provisions, and management of UAS resources. It is not specific to the Gray Eagle, but applies to all categories of UAS employed by the United States Army active duty/reserve/national guard units and supporting civilian contractors.

Flight Regulations, AR 95-1, covers the same topics and is applicable to the same organizations as the *Unmanned Aircraft System Flight Regulations, AR 95-23*, but while it is applicable to UAS, it is not specific to UAS and does not address UAS specific policy. The only UAS specific guidance in this publication is guidance that addresses the recovery operations associated with unmanned aircraft. For the purposes of this study, *Flight Regulations, AR 95-1*, applies directly to the CH-47 and MH-47 units used for this thesis.

1428 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The United States Army Force Management Support Agency (USAFMSA) provides online access to the *Force Management System* website that provides extensive information on how Army units are manned and equipped. For this study, the website was used to access the Modification Table of Organization and Equipment (MTOE) for the Army units used in this study: Company B, 3d Battalion, 82d Combat Aviation Brigade (CF CH-47F unit); Company A, 2d Battalion, 160th Special Operations Aviation Regiment (ARSOA MH-47G unit); Company B, 101st Aviation Regiment (CF MQ-1C unit); and Company E, 160th Special Operations Aviation Regiment (ARSOA MQ-1C unit).

An MTOE is an authorization document that prescribes the modification of a basic Table of Organization and Equipment (TOE). It is a document that prescribes the wartime mission, capabilities, organizational structure, and mission essential personnel and equipment requirements for military units, and adjusts it as necessary to adapt it to the needs of a specific unit or type of unit. For example, the MTOE for an MQ-1C Gray Eagle company shows how many personnel, by grade, and how many airframes, by type, would be required for a company to conduct its wartime mission. For the purposes of this thesis, the different MTOE documents for each of the units being analyzed in this study clearly depicts the differences and similarities between the CF and ARSOA units.

The documents *USASOC Strategy 2035* and *ARSOF 2022* provide guidance for the development of future ARSOF operational and institutional capabilities. For the purposes of this study, these two documents were used to form the basis by which the Chief Decision Maker (CDM) for this study would evaluate the proposed results of this thesis, through the R3: Stakeholder Recommended Solution.

1429 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Conclusion

The review of the cited literature primarily from the military's professional body of knowledge offers insight into the primary and secondary research questions, and also establishes the foundation for the remainder of this thesis. Additionally, this review of literature was conducted in line with the research methodology, using sources from the professional body of knowledge, applicable to the CDM. The next chapter, Chapter 3, will outline the research methodology for this study.

1430 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CHAPTER 3

RESEARCH METHODOLOGY

Purpose of the Research and the Research Questions

The purpose of this study is to persuade the Chief Decision Maker (CDM), the commander of USASOC, that the proposed solutions to E/160's manning, training, and equipping capability gaps, would enable E/160 to provide a unique UAS capability to special operations. The main concerns of the CDM are to obtain next generation unmanned aircraft systems that provide longer operational range and over horizon observation; can be launched and recovered by tactical units; and employ advanced unmanned aircraft systems and intelligence collection capabilities at the tactical level. This includes the concern to provide joint force commanders with professionals who are agile, adaptive, flexible, bold, innovative, and possess a high degree of advanced training; provide the nation with premier special operations forces; and deliver appropriate and effective capabilities to joint force commanders and interagency leaders across the entire spectrum of conflict under any operating conditions. The CDM must broaden the range of special operations aviation-related individual training and education including unmanned aerial systems; and improve army unmanned aerial-system programs of record (Raven, Shadow and Gray Eagle) to meet joint expeditionary tactics, techniques, procedures, forward-based networking and sensor requirements (HQDA 2014a, 24; ARSOF 2035 2017, 3-6).

In order to implement the findings from this research, the CDM would have to utilize the Army Joint Capabilities Integration Development System (JCIDS), the Defense Acquisition System (DAS), and the Planning, Programming, Budgeting, and

1431 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

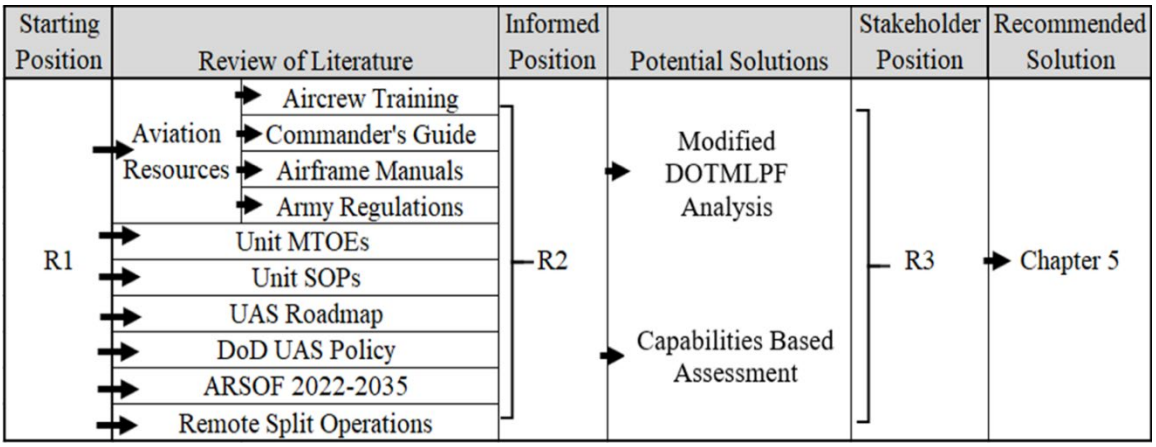
Execution (PPBE) process to develop new solutions to the organization, training, and equipping of USASOC Gray Eagle units (F102Ra 2017, 2). The USASOAC Commander, the 160th SOAR Regimental Commander and the 160th SOAR Battalion Commanders are the other stakeholders who will be influenced by the changes to the units' organization, training, and equipping and who will also be the ones to implement these changes. Additionally, the research findings would have to be in line with current national strategic guidance to include the National Security Strategy (NSS), the National Defense Strategy (NDS), and the National Military Strategy (NMS). The CDM's primary evaluation criteria to assess the results of this research will be based on these available resources: the NSS, the NDS, and the NMS.

In order to answer the primary research question, three secondary questions were developed: (1) How does ARSOA man, train, and equip their UAS units in comparison to both CFs UAS units, and rotary wing ARSOA units? (2) Are there capability gaps in terms of manning, training, and equipping of the ARSOA Gray Eagle organization when compared to the rotary wing ARSOA units? (3) What are the potential materiel and non-materiel solutions to the ARSOA Gray Eagle units' domains of manning, training, and equipping, needed to provide a unique capability to SOF?

To answer these questions, the author conducted a comparative analysis of the literature within the professional body of knowledge dealing with the organization, training, and equipping of ARSOA UAS and rotary wing units, and CF UAS and rotary wing units. The professional body of knowledge primarily included training manuals, technical manuals, Army and Joint Publications, MTOE documents, and Army regulations. This literature illustrated how the units used in this study were organized,

1432 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

trained and equipped. The units were then compared and contrasted to determine capability gaps within the ARSOA Gray Eagle unit. These capability gaps were based on capabilities provided by ARSOA rotary wing units that their CF counterparts were unable to provide. The same analysis was then done with the ARSOA and CF UAS units to determine whether or not ARSOA UAS provided additional capabilities like those provided by the ARSOA rotary wings units.



Research Methodology

The author used an applied professional case study methodology for the study. The applied professional case study is a method of research which is systematic, disciplined, multi-perspective, critical, and designed to both solve a problem and incorporate a research perspective. This case study will inform decision making through the rich description of the environment and recommend a policy by persuasion, reason, and evidence (Long 2016).

This research is an applied professional case study with a modified DOTMLPF-P analysis utilizing a capabilities-based assessment (CBA) to determine potential materiel and non-materiel solutions. The modified DOTMLPF-P analysis utilized the organization, training, and materiel (OTM) domains. The CBA used the professional body of knowledge in the literature review to identify capability gaps and propose material and non-material solutions. The figure and paragraphs below describe the five-chapter format used for this applied professional case study.

1433 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 3. Research Methodology Flow Chart

Source: Created by author.

In Chapter 1, the initial going-in position is captured through the first assessment in the three-part reflective process of the professional applied case study. The R1 assessment, or the initial, personal disposition on the subject is captured in this chapter. This assessment establishes the author's perspective going in and gives credibility to the research by defining what the author knew and felt about the topic prior to conducting the research, as well as establishing any pre-conceived biases going into the literature review.

In Chapter 2, the focus is to review literature from the professional body of knowledge that is both relevant to addressing the research question, and credible to the key stakeholders that the author is trying to persuade. The majority of literature for this research will come from sources within the DOD. These sources of information give the research instant credibility as they come from recognized, credible sources within the same community as the stakeholders the author is trying to persuade.

Chapter 3 describes how the study takes the "raw material" from the literature review and compares the manning, training, and equipping of the ARSOA Gray Eagle

1434 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

unit against ARSOA rotary wing units and CF UAS and rotary wing units. Once the relevant information is broken down and categorized, the study is able to conduct a CBA, focused on a modified DOTMLPF-P analysis, only utilizing the domains of organization, training, and materiel. This process will produce the results necessary to publish the findings in the next chapter.

In Chapter 4, after conducting an objective review of the literature and analyzing the relevant data, the author is able to complete the second assessment, R2. In contrast to the initial assessment, R1 in Chapter 1, the R2 assessment is an updated personal recommendation based on the author's review of the literature (Long 2016).

In Chapter 5, the study makes the final assessment, R3, that are the results from Chapter 4 examined through the lens of the pre-identified CDM and stakeholders that the study is trying to persuade. After the R3, the study takes these findings and uses the Kotter Change Model to address their implementation. Within this process, the research will also identify any new requirements that emerged as a result of the findings. Lastly, the study will address any lessons learned throughout the process. This personal reflection will also address any significant findings throughout the research that fell outside the scope of the research, but are areas that may be worth addressing in a future study.

Conclusion

This chapter provided the background and description of the applied professional case study used to answer the primary and secondary research questions. The benefit of using an applied professional case study as the methodology for this study is that it is a qualitative, complex, and human-centric topic, and it requires a deep understanding of the

1435 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

environment to produce informed decision-making. Specifically, this methodology results in compelling and supported recommendations through the process of organizing and analyzing different types of knowledge/information in a defined setting to enable informed action to improve the current conditions. In the case of this thesis, the research will result in recommendations to enhance the manning, training and equipping of the Gray Eagle company within special operations (Hancock and Algozzine 2011; Gagnon 2010). The next chapter contains the findings of the data collected within this study.

1436 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CHAPTER 4

RESEARCH FINDINGS

Introduction

The purpose of this chapter is to explain the findings of the research and to apply those findings to the applied professional case study methodology. The chapter will be broken down into three parts: the DOTMLPF-P type analysis focused on the domains of organization, materiel, training, and using the capabilities based assessment with the results expressed in the terms of a functional area analysis (FAA), functional needs analysis (FNA), and a functional solutions analysis (FSA); the R2 assessment; and a key stakeholder analysis resulting in the final assessment, R3.

Organization (Manning), Training, Materiel (Equipping) Analysis

The following table depicts the domains of organization, training, and materiel of the components that makeup the CBA, which are functional area analysis, functional needs analysis, and a functional solutions analysis.

1437 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 4. Organization (Manning), Training, Materiel (Equipping) Analysis

	ORGANIZATION	TRAINING	MATERIEL
FAA (Needs)	• Task- Provide C2 for ARSOA UAS employment IAW unit MTOE • Condition- Three simultaneous missions in separate locations • Standard- IAW ARSOA detachment C2 requirements	• Task- Provide specially selected, highly trained, ARSOA 15W operators to support special operations forces • Condition- In support of SOA missions requiring a unique skill or capability to complete. • Standard- IAW ARSOA TC 3-04.11 battle rostering requirements	• Task- Provide a UAS platform with a unique capability to support SOA • Condition- ISO SOA missions conducted outside of current MQ-1C Grey Eagle UAS capabilities • Standard- To support mission sets IAW ARSOA MTOE narrative
FNA (Gaps and Risks)	• Gap- CW4 MTOE allocation as C2 node for 3x separate locations (CONUS/OCONUS) does not meet ARSOA C2 requirements • Risk- UAS detachments in austere locations operating without commissioned, company grade C2	• Gap- ARSOA 15W operators do not have an ARSOA specific training plan or battle rostering process. • Risk- ARSOA 15W operators do not provide a unique skill or capability to support SOA.	• Gap- ARSOA MQ-1C Grey Eagle UAS platform does not provide a unique or additional capability to SOA • Risk- ARSOA MQ-1C Grey Eagle UAS unit unable to support unique SOA missions
FSA (Solution Approaches)	• Non-materiel- Increase O3 MTOE billets to 5x O3 to support C2 requirements for up to 3x simultaneous missions in separate locations • Materiel- Conduct UAS operations through use of RSO with a central MCE	• Non-materiel- Implement a BMQ, FMQ, FLD training equivalent to the ARSOA 15W operator training process.	• Materiel- Modification of MQ-1C Grey Eagle UAS to support expeditionary operations.

Source: Created by author.

Organization (Manning) Analysis

The first FAA on E/160's organization used the unit's MTOE narrative as the basis to determine the task and condition for this analysis. The MTOE narrative states that this unit has the task of supporting up to three simultaneous missions. This narrative also defines the conditions of the task by stating that the unit must be able to support these three simultaneous missions in three separate locations. In order to meet this requirement, E/160 is configured to deploy one CW4 and one E7 as the command and control node for each of the three separate locations. To determine the ARSOA command and control requirements for detached elements conducting operations, this study used a comparative analysis of the MTOE and MTOE narratives from the ARSOA rotary wing

1438 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

company, A/2-160, against the MTOE of E/160. The MTOE narrative for 2-160, which is the battalion that A/2-160 falls under, states that the battalion is not designed to deploy as a whole battalion, but rather as slice elements as part of a Joint Task Force, or as part of a Joint Special Operations Air Component. It also states that the battalion is responsible to provide up to five mission command nodes to simultaneously support split geographic locations. To support this requirement, the MTOE of 2-160 has six commissioned officers, one major and 5 captains, assigned to each rotary wing flight company. E/160's MTOE only has two commissioned officers, one major and one captain. This analysis was used to establish the criteria for commissioned officers in the grade of captain or above and was the standard for geographically dispersed detachment command and control requirements. Additionally, the majority of the battalions in the 160th SOAR mirror the MTOE of 2-160, which reinforced the standard used during the FAA. Importantly, the personal experience of the author attests that CW4s do not serve in a command and control capacity within the 160th SOAR at geographically dispersed locations.

The FNA took the analysis from the FAA to determine any potential capability gaps in the organization of the unit. The first premise that determined the gap in the organization of E/160 was the MTOE comparative analysis. The ARSOA rotary wing companies are manned with an appropriate amount of commissioned officers in the rank of O3 and above to support the detachment command and control requirement as stated in their MTOE narrative. E/160 is manned with CW4s to fulfill their command and control requirement for three geographically dispersed missions. This analysis concludes that the 160th SOAR requires commissioned officers in the rank of O3 and above to act as the

1439 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

command and control elements of geographically dispersed detachments, and identifies a gap in E/160's organization, as E/160 is not able to organically support three geographically dispersed missions with an O3 or above as the command and control element.

This capability gap results in operational risk because it does not give E/160 the organic capability to conduct three geographically dispersed mission sets with a command and control element that meets the requirements of the 160th SOAR. Additionally, this presents risk in the mission approval process for aviation operations at geographically dispersed locations. The final portion of the aviation mission approval process requires the signatures of a mission briefing officer (MBO) and a final mission approval authority (FMAA). The FMAA is the individual that assumes the overall risk of the mission, and assuming risk is primarily the responsibility of commanders in the grade of O3 and above. A CW4 can have FMAA, but it is not the normal process for aviation operations and for that reason it is not included in this analysis of the risk.

The FSA identified a materiel and non-materiel solution to this capability gap. The non-materiel solution would re-allocate MTOE personnel billets of existing human resources in order to fill this capability gap and ensure no increase to the current E/160 MTOE of 165 personnel. The proposed solution would change the five CW4 personnel billets on E/160's MTOE to the grade of O3. This would change paragraph number 102, line number 01, UAS OPERATIONS OFFICER and paragraph number 105, line number 01, UAS PLATOON LEADER, from CW4 allocated billets to O3 billets, which would add five additional O3s to E/160's MTOE. This change would align E/160's MTOE to mirror the rotary wing companies' MTOEs that have six O3 MTOE billets each. This

1440 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

solution would enable E/160 to organically provide a command and control element with an O3 or above to support three geographically dispersed locations at a 1:2 deployment ratio.

The proposed materiel solution to this capability gap would be for E/160 to conduct remote split operations (RSO). RSO would solve this capability gap by providing a central mission control element (MCE) at E/160's home station to provide command and control of three geographically dispersed locations. E/160 would have two commissioned officers in the grade of O3 and above to provide command and control of three launch and recovery elements (LRE) at three geographically dispersed locations. This is a materiel solution because it would require an investment to the current communications architecture in order for E/160 to conduct RSO.

The second FAA on E/160's organization used Army doctrine, *ADRP 3-05 Special Operations,* and Joint doctrine, *JP 3-05 Special Operations,* to establish the task for this analysis. Of note, the author did not include this second analysis in the table at the beginning of this chapter because while the following analysis is relevant and identified a follow-on research question in chapter five, it did not make it past the author's updated individual recommendation and would not be brought before the CDM in the R3. These guiding doctrinal references state that in order to be a special operations unit, the unit must be specially organized, trained, and equipped. The FAA task in terms of organization is that E/160 must have more senior and experienced 15W Gray Eagle operators. Army and Joint doctrine also provide the condition for this analysis, that E/160 must be able to provide special operations forces with a unique capability in terms of employment, tactics, techniques, procedures, and equipment. An increase in the grade of

1441 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

15Ws assigned to E/160 would provide this unique capability, differentiating E/160 from conventional MQ-1C Gray Eagle units. To determine the standard for the FAA, this study used an MTOE comparative analysis of ARSOA rotary wings units to CF rotary wing units and compared them to ARSOA Gray Eagle in relation to CF Gray Eagle formations. This established the standard set for this study. The graphs below illustrate that airframe operators, in this case MH-47/CH-47 pilots and MQ-1C Gray Eagle 15W operators, are more senior in ARSOA rotary wings units compared to CF rotary wing units, but that is not the case for ARSOA Gray Eagle operators.

The number of personnel must be taken into account when viewing this graph since the ARSOA units have a higher overall number of personnel assigned than the CF units.

Table 5. Operator and Pilot Analysis

MQ-1C OPERATORS BY GRADE	E/160TH SOAR	B/101ST ABN
E-7	4	3
E-6	8	6
E-5	16	9
E-4	24	16

H-47 PILOTS BY GRADE	A/2-160TH SOAR	B/3-82ND
W4	8	0
W3	13	3
W2	0	17

Source: Created by author.

The A/2-160's MTOE total is 139 personnel, compared to B/3-82's MTOE of 52 personnel, and E/160's MTOE total of 165 personnel, compared to B/101's MTOE of

1442 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

127 personnel. Even with the overall MTOE number taken into account, it is clear that A/2-160 has more senior pilots than B/3-82. A/2-160 has no CW2s assigned while the majority of pilots assigned to B/3-82 are made up of CW2s. Conversely, B/3-82 has zero CW4s assigned while A/2-160 has eight. When looking at the MTOEs of E/160 and B/101, the same differences are not evident. When the difference in overall MTOE personnel assigned is taken into account, the operators by grade are essentially the same for E/160 and B/101. Since the overall majority of ARSOA has MTOEs that mirror A/2-160, this analysis determined that the standard for ARSOA is to have more senior pilots and operators than the CF counterparts.

The FNA took the analysis from the FAA to determine any potential capability gaps in the organization of the unit. The first premise that determined this gap in E/160's organization was the MTOE comparative analysis. The ARSOA rotary wing companies are manned with pilots of a higher grade than the CF rotary wing units. This comparison illustrated a gap in E/160's capability because when compared to the MTOE of B/101, the operator by grade, is essentially the same. This is a capability gap, because E/160 is not specially manned to support special operations, as compared to ARSOA units.

This capability gap results in operational risk by not providing a unique capability in terms of organization to special operations because E/160 does not have more senior Gray Eagle operators than CF Gray Eagle units. Part of ARSOA's ability to provide a unique aviation capability to special operations is by manning the rotary wing units with more senior pilots to conduct ARSOA missions. ARSOA mitigates risk and is able to conduct operations that CFs are unable to accomplish, in part, because ARSOA has deliberately organized its rotary wing units with senior grade pilots. E/160 does not have

1443 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

this same organization, which increases the risk of conducting unique missions in support of special operations.

The FSA used the analysis of the ARSOA rotary wing unit, A/2-160, presented in this study, as the basis for the recommended materiel solution. The materiel solution would be to increase MTOE billets of the enlisted Gray Eagle 15W operators in the grades of E5, E6, and E7. This solution would not add additional personnel to E/160's overall personnel count of 165, but would take those billets from the E4 15W billets. This change is in line with the organization of A/2-160, as that unit's pilot billets have no CW2s, and only have MTOE billets in the grade of CW3 and above. The increase of E5, E6, and E7 15W MTOE billets would increase the overall experience level of 15W operators to match the capabilities provided by ARSOA rotary wing units. Additionally, increasing E7 15W MTOE billets within E/160 will enable experienced operators to remain within the unit, increasing the unit's capability. Currently, E/160 only has four E7 15W MTOE billets, as UAS PLATOON SERGEANTS, that focuses those E7 15W operators on the leadership and administrative requirements of the platoon. In comparison, A/2-160 has CW4 MTOE billets at the platoon level as SR IP/IFE, which is a position that focuses on the tactical employment of the MH-47G. This analysis illustrates that ARSOA rotary wing units have MTOE billets that enable their most experienced pilots to remain at the platoon level that adds a unique capability in terms of organization and manning, that the CF does not. This materiel solution to E/160's manning would enable them to provide the same capability as the ARSOA rotary wing units.

1444 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Training Analysis

The FAA on E/160's training also used Army doctrine, *ADRP 3-05 Special Operations,* and Joint doctrine, *JP 3-05 Special Operations,* to establish the condition for analysis focused on distinctive capabilities required of special operations forces. This study used the unique ARSOA mission battle-rostering requirements in accordance with *ARSOA 3-04.11* as the basis for the standard in the FAA. This standard determined that battle-rostering within special operations aviation is unique and ensures the ground force commander has support by providing a clear tool to control risk while retaining mission flexibility. ARSOA accomplishes this through its unique battle-rostering, which organizes crews by mission qualification.

The FNA took the analysis from the FAA to determine potential capability gaps in unit training. The analysis determined that E/160 does not have an ARSOA specific mission training process for 15W Gray Eagle operators. The ARSOA rotary wings units have a unique training and battle-rostering process that uses the aircrew mission designations of BMQ, FMQ, and FLD to provide a unique, special operations specific, capability. E/160 uses the same battle-rostering process as conventional Gray Eagle units and does not have unique, special operations aviation specific aircrew designation of BMQ, FMQ, and FLD. This study used this analysis to define this as a training capability gap within E/160.

The risk associated with this capability gap is that there is an expectation from supported special operations forces that ARSOA provides a unique Gray Eagle capability, and part of that expectation involves uniquely trained 15W operators. This expectation is determined by both the doctrinal definition of a special operations unit and by the precedent set by ARSOA rotary wing over the past 36 years. ARSOA rotary wing

1445 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

units use their unique battle-rostering process to reduce risk for the ground force commander during aviation operations. Without a unique, mission tailored battle-rostering process, E/160 cannot provide the same risk reduction capability to the ground force commander that the ARSOA rotary wing units provide.

The FSA used the unique ARSOA rotary wing mission training process as the basis for this solution. The proposed non-materiel solution to this capability gap would be for E/160 to implement an ARSOA specific 15W operator training and mission battle-rostering process that mirrors the ARSOA rotary wing units. This would include adding additional aircrew designations, like BMQ, FMQ, and FLD, to the unit's aircrew training programs that would enable E/160 to battle-roster their crews to tailor specific mission requirements. This would enable E/160 to provide a unique special operations Gray Eagle capability to the ground force commander that would enable them to control risk while retaining mission flexibility.

Materiel (Equipping) Analysis

The FAA related to materiel (equipping) also used Army doctrine, *ADRP 3-05 Special Operations,* and Joint doctrine, *JP 3-05 Special Operations,* to establish the task for analysis focused on distinctive capabilities required of special operations forces. To define the standard for the FAA, this study used a comparative analysis of the airframe operator's manuals from the different units included in this study. This comparison illustrated that the ARSOA rotary wing unit, A/2-160, has a modified version of the CF Army CH-47F Chinook, heavy lift rotary wing. A/2-160 employs the MH-47G Chinook, a heavy assault rotary wing which provides special operations forces with a unique piece of equipment that provides additional capability to special operations. For example, the

1446 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

MH-47G has an in-flight refuel capability that provides special operations forces with a long-range infiltration capability not provided by the CF's CH-47F. When this same comparison is made between the ARSOA and CFs Gray Eagle units, there is no specialized equipment that enables E/160 to provide an additional capability to special operations forces. The Gray Eagle employed by E/160 is identical to the one employed by the CF Gray Eagle unit, B/101. Given the results of this comparison, this study then used the MTOE narrative of the ARSOA rotary wing units to define the standard that states the unit has unique equipment, tailored to support specific mission profiles.

The FNA used the analysis from the FAA to determine any potential capability gaps in the equipping of the unit. The analysis determined that E/160 does not have equipment that provides a unique capability to the ground force commander like the ARSOA rotary wing units. To further define the possible equipment capability gaps, this study used three unique capabilities provided by ARSOA rotary wing units in comparison to CF's rotary wing units. These capabilities are extended range, advanced aircraft survivability equipment, and advanced onboard radar allowing rotary wing operations in degraded environmental conditions. These equipment capabilities provide a unique capability to support the ground force commander over those that exist within the conventional forces (CF). This illustrates an equipment capability gap for E/160, because their equipment does not provide a unique capability in comparison to the CF Gray Eagle units.

The risk associated with the identified equipment capability gap is that E/160, in terms of UAS support, does not offer the ground force commander a unique capability to execute missions that are outside of the CF's Gray Eagle capability. Special operations

1447 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

require a unique equipment capability because they are often conducted in denied or hostile environments, under unfavorable weather and environmental conditions, and require real time intelligence. As an intelligence, surveillance, and reconnaissance platform in support of special operations, E/160 has to have a unique capability that can operate in conditions that exceed the ability of those found in the CF units.

The FSA used the unique capabilities provided by the ARSOA rotary wing units as the basis for this solution. The proposed materiel solution would be for ARSOA to invest in research and development to modify the Gray Eagle to provide a unique UAV platform capability specifically designed to support the special operations community. The specific modifications should be the focus of a follow-on study; however, based on the author's operational experience, the author would recommend two potential materiel solutions to the current Gray Eagle company equipment resources to enhance its ability to support special operations. First, the engineers should reduce the size of the ground control station, satellite and ground data terminals, and secondly, they should reduce the total amount of ground support equipment required to operate the Gray Eagle to improve the company's expeditionary capability.

R2: The Updated Individual Recommendation

The R2: Updated Individual Recommendation is composed of the same questions that were answered in the R1: Initial Personal Recommendation. The difference is that these same questions will be answered after conducting the literature review. This illustrates the changes in opinion and recommendation after completing a review of the relevant literature. The R2 provides credibility to the applied professional case study methodology by demonstrating to the reader the changes in perception by the author after

1448 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

completing the literature review. The R2: Updated Individual Recommendation will only address significant changes from the R1: Initial Personal Recommendation.

The first part of the R2 discusses the primary research question and why it is important to the author and the key stakeholders within the United States Army Special Operations Command (USASOC). When this research effort was initiated the primary research question in this study was framed as: how should United States Special Operations Command adapt manning, training, and equipping of the ARSOA Gray Eagle unit to provide the unique capabilities required by the special operations community? Joint and Army doctrine both define special operations as activities requiring unique capabilities not provided by the CF. Doctrine also affirms that special operations forces must be specially organized, trained, and equipped to provide this unique capability (ADRP 3-05, 2012; JCS 2011). After analyzing the similarities and differences of a CF Gray Eagle company to an ARSOA Gray Eagle company and comparing them to the similarities and differences between a CF rotary wing company and an ARSOA rotary wing company, it is evident that there are gaps in capabilities provided by the ARSOA Gray Eagle company. Specifically, the manned ARSOA rotary wing company analyzed in this study provides unique special operations capabilities because it is specifically manned, trained, and equipped differently than the CF rotary wing company analyzed in this study. However, the same cannot be said about the ARSOA MQ-1C Gray Eagle company in comparison to the CF MQ-1C Gray Eagle company. This new knowledge and understanding led the author to update the primary research question to: are there organizational (manning), training, and materiel (equipping) capability gaps that are

1449 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

preventing the ARSOA Gray Eagle unit from providing a unique special operations aviation capability?

During the course of this study, the author was informed that upon completion of the Command and General Staff College, he would be taking command of the newly fielded ARSOA Gray Eagle company, Company F, 160th Special Operations Aviation Regiment, scheduled to officially activate in August of 2018. In turn, this made the author a stakeholder in this research at the tactical level and more invested than at the beginning. The review of literature also defined the stakeholders' position and established the basis that the CDM will evaluate this study through the R3: Stakeholder Recommended Solution, presented in the final assessment.

The second part of the R2 addresses why this study is important and the possible consequences if this topic is not addressed. The new ARSOA Gray Eagle company, F/160, is scheduled to activate in August 2018 and results in the fielding of two ARSOA Gray Eagle companies within a five-year period. This highlights the importance that the DOD is placing on the development of UAS within ARSOA. The review of literature confirmed the author's initial position and opinion that the UAS capability provided to special operations aviation must provide a unique capability not provided by the CF Gray Eagle units. Additionally, the earlier that these gaps can be identified and validated by the CDM, the earlier the solutions can be implemented.

The final portion of the R2 identifies the potential solutions to the problem statement identified through the review of literature. The review of literature identified gaps within the manning, training, and equipping of the ARSOA Gray Eagle company. The primary sources of data for this study were DOD publications. The MTOE

1450 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

documents for the four units used in this study provided a clear comparison of the CF and ARSOA Gray Eagle companies in relation to the ARSOA and CF rotary wing companies. This analysis provided evidence to support a capability gap in the manning of the ARSOA MQ-1C Gray Eagle company. The MTOE narrative and aircrew training publications provided the necessary information to compare and contrast the training requirements and processes within the different ARSOA and CF companies used in this study. This provided insight on gaps within the training domain of the ARSOA Gray Eagle company. Lastly, by comparing airframe specific technical manuals, it was evident that there was no unique equipping capability provided by the ARSOA Gray Eagle company in comparison to the CF's UAS company. In contrast, by comparing the airframe specific technical manuals of the ARSOA and CFs rotary wing companies, ARSOA aircraft provided a unique equipping capability when compared to the CF's. By identifying these gaps and the risks associated with them, the potential materiel and non-materiel solutions for each were identified and explained earlier in this chapter.

R3: Stakeholder Recommended Solution

To determine the R3: Stakeholder Recommended Solution, the author evaluated the R2 through the lens of the Chief Decision Maker (CDM) and the stakeholders. The CDM for this applied professional case study is the Commander of the United States Army Special Operations Command (USASOC), the stakeholders include the 160th SOAR Regimental Commander, and to a smaller extent, the 160th SOAR Battalion Commanders. The USASOC Commander was chosen as the CDM as opposed to the Commander of United States Special Operations Command (USSOCOM) because the purpose of this applied professional case study is to persuade the CDM in order to affect

1451 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

change. The USSOCOM Commander already employs Group 4 UAS within the other services, but this study is specific to employment of the Gray Eagle within ARSOA, which is focused on the Army and its mission of unified land operations, "to apply land power as part of unified action to defeat an enemy on land and establish conditions that achieve the JFC's commander's end state" (FM 3-0 2017, 34; USSOCOM Fact Book 2017, 49). This means that the USASOC Commander must be persuaded that the ARSOA Gray Eagle needs to provide a unique UAS capability to enhance ARSOA before these potential solutions are presented to the USSOCOM Commander.

ARSOF 2022 and *USASOC Strategy-2035* comprised the literature used as the basis for the CDM's concerns. Additionally, the concerns presented were compared to the 2018 USSOCOM Posture Statement made by the Commander, General Raymond A. Thomas, on February 15, 2018 before the House Armed Services Committee, to ensure that these concerns are nested within the next higher echelon of command. The main concerns of the CDM were to:

- Obtain next generation unmanned aircraft systems that provide longer operational range, over horizon observation, and can be launched and recovered by tactical units;
- Employ advanced unmanned aircraft systems and intelligence collection capabilities at the tactical level; provide joint force commanders with professionals who are agile, adaptive, flexible, bold, innovative, and possess a high degree of advanced training;
- Provide the nation's premier special operations forces, delivering appropriate and effective capabilities to joint force commanders and interagency leaders across the entire spectrum of conflict and under any operating conditions;
- Broaden the range of special operations aviation-related individual training and education including unmanned aircraft systems; and
- Improve army unmanned aircraft system programs of record (Raven, Shadow and Gray Eagle) to meet joint expeditionary tactics, techniques, procedures, forward-

1452 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

based networking, and sensor requirements (HQDA 2014a, 24; ARSOF 2035 2017, 3-6).

The first part of the R3 will discuss the primary research question and why it is important to the CDM, the Commander of United States Army Special Operations Command (USSOCOM). The primary research question for this study is: are there organizational (manning), training, and materiel (equipping) capability gaps that are preventing the ARSOA Gray Eagle unit from providing a unique special operations aviation capability? The primary research question in this study is directly in line with the CDM's position because it specifically addresses the objectives for improved UAS capabilities within special operations as defined in *ARSOF 2022* and *USASOC Strategy-2035*. However, the CDM would disagree with the premise that E/160 does not provide a unique special operations aviation capability. The CDM would argue that the unique capability provided by E/160 is that it is manned and equipped to support three geographically dispersed mission sets simultaneously, as stated in the MTOE narrative, "this unit was specifically designed to meet SOA requirements for multiple simultaneous deployments to widely separated areas." From a manning perspective this is clearly evidenced by E/160's MTOE total of 165 personnel, compared to B/101's MTOE of 127 personnel. However, from an equipping perspective, both E/160 and B/101 are supplied with the same amount of equipment that makes up the UAS company; 12 x unmanned aerial vehicles (UAVs), 6 x ground control stations (GCSs), 6 x ground data terminals, and 3 x satellite ground data terminals. E/160 is equipped with slightly more ground support equipment, specific to the UAS, and has three additional generators. This means that from a purely equipment perspective, B/101 could support three geographically dispersed mission sets simultaneously, just like E/160.

1453 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The second part of the R3 addresses why this study is important and the possible consequences if this topic is not addressed. In contrast to the author, the CDM would have to take into account competing resources when reviewing the results of this study. The CDM is responsible for a much bigger organization than what the author addresses in the R2, meaning that this study would have to persuade him to believe that the capability gaps addressed in this study outweigh other requirements in the USASOC enterprise. This would make the consequences to the CDM very different than the consequences stated by the author, while acknowledging that the CDM may face other consequences in the USASOC enterprise by electing to use valuable resources to pursue any of these proposed materiel solutions.

The final portion of the R3 takes the recommended solutions from this study and filters them through the lens of the CDM. The first organizational (manning) capability gap identified in this study was the lack of commissioned, company grade and above officers to perform the command and control requirement for three geographically dispersed mission sets. The two recommended solutions to this capability gap were to conduct RSO or to increase the O3 MTOE billets to six. The CDM views RSO as a viable option for ARSOA to employ its Gray Eagle assets. The author's personal operational experience attests that DOD conducted a study into RSO for ARSOA, but due to classification cannot disclose the findings or implications for future ARSOA employment.

The second recommended solution, to increase O3 MTOE billets, would not be accepted by the CDM for two reasons. First, this solution does not address any of the CDM's chief concerns. Second, it would not be feasible with respect to personnel

1454 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

limitations within ARSOA. Additionally, E/160 is attached to 2d Battalion, 160th SOAR, that the CDM would argue has the ability to support E/160 with its O3 command and control requirements to support three simultaneous, geographically dispersed missions. The second organizational (manning) gap addressed by the author was the need to increase the 15W MTOE billets of E5, E6, E7, and to reduce the number of E4s. The CDM would not approve this solution because it does not fall within his main concerns. The CDM is concerned with broadening the range of special operations aviation-related individual training and education including unmanned aerial systems, and would invest in that as opposed to the additional cost of increasing the rank structure of the 15Ws.

The training capability gap addressed in this study is that E/160 does not have an ARSOA specific mission training process for 15W Gray Eagle operators. The proposed non-materiel solution to this capability gap would be for E/160 to implement an ARSOA specific 15W operator training and mission battle-rostering process that mirrors the ARSOA rotary wing units. The CDM would approve this proposed solution because it meets all the criteria of an FSA, is non-materiel, and is in-line with his concern of broadening the range of special operations aviation-related individual training and education including unmanned aerial systems.

The materiel capability gap addressed in this study is that E/160 is not equipped to provide a unique ARSOA UAS capability. The proposed materiel solution would be for ARSOA to invest in research and development to modify the Gray Eagle to provide a unique aviation capability. The author recommended a modification to the Gray Eagle that increases its expeditionary capability by reducing the physical size of the ground control station, and satellite and ground data terminals as well as reducing the total

1455 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

amount of ground support equipment required to operate the Gray Eagle. The CDM would agree with the author's recommendation to conduct research and development into the modification of the Gray Eagle to increase its expeditionary capability. This recommendation is in-line with the CDM's concern of improving Army unmanned aircraft-system programs of record (Raven, Shadow and Gray Eagle) to meet joint expeditionary tactics, techniques, procedures, forward-based networking, and sensor requirements.

Conclusion

This chapter explained the findings of the research and applied those findings to the applied professional case study methodology. The modified DOTMLPF-P analysis provided recommended solutions to the CDM through the use of a CBA. These proposed solutions were then vetted by the CDM, through the final assessment, the R3. The next chapter, Chapter 5, will address the final recommendations of this study.

1456 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CHAPTER 5

CONCLUSIONS AND RECOMMENDATIONS

Recommended Solutions

This section will discuss the implementation plan for the two recommended solutions proposed by this study. The implementation plan is broken down into short term (one to two years) and long term (three to five years) time frames and will use the principles of the Kotter Change Model for implementation. The two proposed solutions are a direct result of the author's professional operational experience in ARSOA, extensive literature review based in the professional body of knowledge that exists for this topic, and the analysis of that knowledge through the use of the applied professional case study methodology.

The United States Army is an organization that is not always willing to acknowledge and embrace the need for change. There are many ways to accomplish change within an organization and one that is both appropriate for this study and used in Army doctrine is the Kotter Change Model, hereafter referred to as the Kotter Model. This model uses the following eight-step process to affect change within an organization.

The first step in the Kotter Model is to establish a sense of urgency. This is done by creating a climate within the organization that is dissatisfied with the status quo by setting aggressive goals and objectives that force the organization to make significant change and overcome complacency.

The second step is to create the guiding coalition. After establishing a sense of urgency, a group of senior, influential, and respected individuals within the organization

1457 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

that support and are fully committed to implementing the change must be formed to propel the change forward.

The third step is to develop a vision and a strategy. Once the guiding coalition is formed, that group is used to develop a feasible vision and strategy that is imaginable, desirable, feasible, focused, flexible, communicable, provides an imaginable picture of the future, a shared sense of purpose, focuses efforts, aligns priorities, and sparks excitement for members of the organization.

The fourth step is to communicate the change vision. This is one of the most important stages within the process. Simply creating a vision and strategy to affect change accomplishes nothing unless the entire organization knows what the vision is and why it is so important for the organization to undertake.

The fifth step is to empower broad-based action. This involves empowering subordinate leaders that are committed to the change, potentially removing leaders that oppose it, creating an environment of decentralized control, and developing a shared understanding with mutual trust.

The sixth step is to generate short term wins. These accomplishments enable the organization to see tangible results toward accomplishing the desired change, which in some cases could take years to complete. Identifying and rewarding these short term gains helps to maintain the momentum of the change effort.

The seventh step is to consolidate gains and produce more change. Consolidating the effects garnished from the short terms wins will open the change initiative to other areas within the organization that were not evident at the start of the change process.

1458 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Identifying these other changes and capitalizing on them during the process is essential to preventing regression while maintaining the momentum for further change.

The eighth and final step is to anchor the new approach into the culture. Kotter defines culture as, “norms of behavior and shared values among a group of people”. This final step is vital as it is the point where the organization as a whole, believes that the new process is the way the organization now does business and ensures the practice remains even if the current leadership at the time of the change, switches out (Miller and Turner 2017, 1-8)

The proposed solution identified for short term implementation (one to two years) is to implement an ARSOA-specific 15W operator training and mission battle-rostering process that mirrors the ARSOA rotary wing units. This change to the training domain of ARSOA Gray Eagle units would be a fairly simple change to make. This is because the process for this type of training plan is already in place for the ARSOA rotary wing units. This is a mission specific training program and could theoretically be implemented with minimal increase to the individual operator required flight hours. Affecting this change would not necessarily have to be approved by the Chief Decision Maker (CDM), but could be implemented by the other stakeholders, most likely by the 160th SOAR Commander. Additionally, because this is a non-materiel solution, it is very realistic for short term implementation. This proposed solution was recommended because it is nested within the main concerns of the CDM, as stated in *ARSOF 2022* and *USASOC Strategy-2035*, that include: (1) provide joint force commanders with professionals who are agile, adaptive, flexible, bold, innovative, and possess a high degree of advanced training, and

1459 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

(2) broaden the range of special operations aviation-related individual training and education including unmanned aircraft systems.

Using the principles of the Kotter Model, the author recommends the following short term implementation plan for the proposed change to the training domain of the ARSOA Gray Eagle units. It is once again important to note that the author will be taking command of the newly fielded ARSOA Gray Eagle company, F/160, with an activation date set for August 2018, and will attempt to affect this proposed change to the training domain of F/160. The author's professional operational experience attests that the biggest obstacles to implementing this change will be with steps one and two of the Kotter Model. The first ARSOA Gray Eagle company, E/160, is viewed as a critical capability within the SOF community, and because of that, the author believes that establishing a sense of urgency, as well as forming a guiding coalition will be difficult. The argument to overcome this is that the ARSOA rotary wings success over the past 36 years is directly attributed to this process of training. Additionally, because this process is already in use by the ARSOA rotary wing units, step three of the Kotter Model will be extremely easy to produce, since it already exists. That is also why the author believes that this recommendation is so viable, because the organization has already bought into the process and can easily identify with it. The challenge will be in convincing the other stakeholders, as well as the senior members of the unit, that this process can be as beneficial for the ARSOA Gray Eagle community as it is for the ARSOA rotary wing community.

After garnishing support for this recommended change, the next biggest task will be to generate short term wins in order to ensure this change gains momentum and

1460 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

becomes part of the established training process within the organization. The immediate result of applying this training process within the organization, will be the increased confidence that the individual operators will have when conducting their mission and specifically with their ability to conduct professional air mission briefs. The ARSOA mission training process involves extensive training in the process of conducting professional military air mission briefings. Making that a part of the ARSOA 15W training process will dramatically increase their confidence in their briefing abilities and propel this change forward from the bottom up. With a bottom up approach, this will ensure the majority of the company buys into the new training process which will help to confirm this solution with the organization's leadership and stakeholders.

Once the recommended training process is established at the company level, this implementation plan will look to consolidate gains and further the change process by establishing this recommended change at the battalion and regimental levels. To accomplish this, the training process will first need to be standardized within the battalion and then, to anchor the change, written into the regimental standard operating procedure. Once the process is refined and standardized enough to be written into the official regimental standing operating procedure, it will ensure that this process is the approved way that the organization does business, and will remain in place once the implementing leadership switches out.

The proposed solution identified for long term implementation (three to five years) would be for ARSOA to invest in research and development to modify the Gray Eagle to provide a unique aviation capability to the SOF community. It is important to note that this recommendation was selected for long term implementation because

1461 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

ARSOA is currently scheduled to conduct the full operational testing and evaluation of the MQ-1C Gray Eagle Extended Range UAS in July of 2018. This new version of the Gray Eagle will provide additional capabilities and, because of this, it is unlikely that the CDM will have an appetite for any additional investment into research and development of the Gray Eagle until the added benefits of this new version are fully understood. It is also important to note that while ARSOA is conducting the full operational testing and development of the MQ-1C Gray Eagle Extended Range UAS, this new version will be fielded to both ARSOA and CF Gray Eagle units and the new capability will not be unique to the SOF community.

The specific modification to the Gray Eagle should be the focus of a follow-on study. Based on the author's operational experience, the author would recommend a modification that would increase its expeditionary capability, specifically by reducing the size of the ground control station, satellite and ground data terminals, and reducing the total amount of ground support equipment required to operate the Gray Eagle. This proposed solution was recommended because it is nested within the main concerns of the CDM, as stated in *ARSOF 2022* and *USASOC Strategy-2035*, that include: (1) obtain next generation unmanned aircraft systems that provide longer operational range, over horizon observation, and can be launched and recovered by tactical units, and to (2) improve army unmanned aircraft system programs of record (Raven, Shadow and Gray Eagle) to meet joint expeditionary tactics, techniques, procedures, forward-based networking, and sensor requirements.

Using the principles of the Kotter Model, the author recommends the following long term implementation plan for the proposed change to the materiel domain of the

1462 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

ARSOA Gray Eagle units. Unlike the proposed short term solution, the identified long term solution is simply a recommendation to invest in research that will lead to a change in the future. For this reason, the implementation plan will not use all eight steps of the Kotter Model, but will focus on Steps One and Two. The author believes that creating a sense of urgency and building a guiding coalition among the CDM and stakeholders for this recommended solution will be difficult, given the fact that a new version of the MQ-1C Gray UAS is currently being fielded. The key to overcoming this obstacle is to emphasize to the CDM and stakeholders the fact that the new version of the Gray Eagle was based upon the needs of the CF, and that a SOA specific research and development process has not been conducted to meet SOF specific UAS needs. This will remain in line with ARSOA common practice, as the rotary wings employed by ARSOA were modified based on SOF specific operational needs, and that the same should hold true for the platform employed by the ARSOA UAS units.

Recommendations for Further Study

The first recommendation for further study would be to increase the expeditionary capability of the Gray Eagle by reducing the size of the ground control station, satellite and ground data terminals, and the amount of ground support equipment required to operate the Gray Eagle. The study would need to focus on the current breakdown and buildup times of the Gray Eagle in its current configuration as well as the amount of pallet space aboard United States Air Force (USAF) aircraft that is required to move one Gray Eagle flight platoon from one location to another. The study would then need to establish the timeline and cargo requirements needed to support United States Special Operations Command (USSOCOM) type of mission sets. Once this baseline is

1463 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

established, the study would be able to determine the specific requirements needed to publish the Operational Needs Statements (ONS) request to industry leaders and produce a modified version of the Gray Eagle to address the capability gap in supporting this USSOCOM mission set.

The second recommendation for further study would be to further research the capability provided by using Remote Split Operations (RSO) to employ ARSOA UAS. As stated earlier in this thesis, the professional operational experience of the author attests that there has been a study conducted on RSO, but due to classification cannot publish the results. However, the author would argue that another study needs to be conducted looking specifically at the benefits gained by the communication architecture needed to conduct RSO. In addition to the expeditionary and manning benefits of RSO, the author believes that RSO would also benefit the training level of 15W operators.

Affording 15W operators different training environments is difficult due to the fact that UAS operations within the national airspace are very hard to conduct. Currently, the process involved with transiting the national airspace with a UAV is next to impossible because of the restrictions imposed by the Federal Aviation Administration (FAA). This forces ARSOA Gray Eagle units to exclusively train at their home base or incur the high costs of transporting all the equipment necessary to operate at another US location. The author believes that these costs could be greatly reduced by the infrastructure associated with conducting RSO, which would make training at different locations within the United States more of a reality. The study would need to look at a cost analysis of being able to move a relatively small UAS package, due to the communication architecture of RSO, from one location to another, in order to train with

1464 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

different SOF units across the United States. The author believes that by conducting this analysis, the CDM and stakeholders would see another benefit of RSO that has not been previously addressed.

The final recommendation for further study would be to further research small precision guided munitions. The Gray Eagle needs to have the ability to tailor its payload based on the mission set. Weight will always be a factor regarding UAS operations and further research needs to be conducted to find an alternate payload for the Gray Eagle other than its current restriction to the Hellfire missile. This is not to say that the Hellfire is not an effective munition for the Gray Eagle, but in its current configuration, it can only carry up to four Hellfire missiles. This recommendation for further study would be to give the Gray Eagle an alternate, lighter, precision guided munition that would provide the ground force commander with more options when supporting different mission sets.

In addition to the aforementioned recommendations, the author and his thesis committee members developed four additional recommendations for further study after conducting the formal thesis defense. The four recommendations for further study are: (1) What are the training requirements that will be driven by an upgraded Gray Eagle materiel solution? (2) Perform a manpower grade analysis to document personnel requirements in the grades of O3 and CW4, for six MTOE positions. (3) Determine if ARSOA manning policy needs to be amended to account for UAS needs. (4) Conduct a SOF specific mission analysis for UAS platforms to define materiel key performance parameters.

1465 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Personal Learning Reflections

By conducting this research, the author gained a clear understanding of the current capabilities of the ARSOA Gray Eagle units, and more importantly, an understanding of the current capability gaps in the domains of organization, training, and materiel. As a future stakeholder in this community, this research enabled the author to develop a vision and strategy for commanding the newly fielded ARSOA Gray Eagle company, F/160. Additionally, by focusing this study within the professional body of knowledge associated with this topic, the author was able to both confirm and reject various biases that were held prior to conducting this study. This is significant, as the applied professional case study methodology ensured that the author's understanding of this topic moving forward is objective and based solely on the credible literature that was reviewed during the study.

In addition to his own professional growth, the author believes that this study is the first step for the ARSOA UAS community to begin to define its role within SOA. The Gray Eagle platform was designed to meet the needs of the CF and this paper has illustrated the fact that while this current capability is successful in ARSOA, it is now at the point where ARSOA needs to modify the current capability for SOA. Just like the ARSOA rotary wing units took CF rotary wing organizations and modified them to meet SOA specific needs, the ARSOA Gray Eagle units need to begin making the same organizational, training, and materiel modifications to support specific SOA needs.

14. ABSTRACT
This report details the measurement of sound levels around a Shadow and a Gray Eagle unmanned aircraft system (UAS). Sound levels inside of Universal Ground Control Stations (UGCS) were also measured. The results indicate the Shadow UAS operator should be well protected using the David Clark H10 headset. The Gray Eagle operators did not wear hearing protection and it is recommended that they use some sort of hearing protection. The sound levels in the measured UGCSs were relatively low and the RACAL RA5000/1/1026 Raptor headsets that are currently being used will provide more than adequate hearing protection.

Summary

An unmanned aircraft system (UAS) is an unmanned aircraft (UA) with associated support equipment, control station, data links, telemetry, communications, and navigation equipment necessary to operate it (FDOT, 2019). USAARL tested sound levels produced by two different UA systems—the RQ-7Bv2 Shadow and MQ-1C Gray Eagle. The RQ-7 Shadow Tactical Unmanned Aircraft System (TUAS) provides reconnaissance, surveillance, target acquisition, and force protection for the Brigade Combat Team (BCT) in near-real-time during day, night, and limited adverse weather conditions. The MQ-1C Gray Eagle is a medium-altitude, long-endurance (MALE) UAS and is an upgrade to the MQ-1 Predator UAV drone line.

The purpose of this test was to determine the sound level around the Shadow and Gray Eagle UASs and inside the universal ground control station (UGCSs). The study also looked at the effectiveness of headsets currently used with those systems.

Results indicated that sound levels around the Shadow and Gray Eagle require the use of hearing protection per Section 7-13 of DA PAM 40-501 which states that appropriate hearing protection must be worn when working with or around aircraft that produces exposure to steady state noise levels of 85 dB(A) of *any* duration. The Shadow (at the operator position) reaches a maximum sound level of 98dB(A). The Grey Eagle produces sound levels of 87 dB(A) next to the UAS on the right side, and a measurement of 92 dB(A) underneath during short intervals of time. Sound levels inside the UGCS do not reach the threshold to require additional hearing protection per Section 7-13 of DA PAM 40-501.

Results related to the evaluation of the current headsets being used by UAS operators indicate that Shadow UAS operators should be well protected using the current David Clark H10 headset. However, it is recommended that Gray Eagle operators use some sort of hearing protection. The sound levels in both UGCSs were relatively low and the RACAL RA5000/1/1026 Raptor headsets that are currently being used provide more than adequate hearing protection.

Introduction

An unmanned aircraft system (UAS) is an unmanned aircraft (UA) with associated support equipment, control station, data links, telemetry, communications, and navigation equipment necessary to operate it (FDOT, 2019). The focus of this test is to accurately quantify sound levels produced by two different UA systems. The two systems tested are the RQ-7Bv2 Shadow and the MQ-1C Gray Eagle. The RQ-7 Shadow Tactical Unmanned Aircraft System (TUAS) provides reconnaissance, surveillance, target acquisition and force protection for the Brigade Combat Team (BCT) in near-real-time during day, night and limited adverse weather conditions. The MQ-1C Gray Eagle is a medium-altitude, long-endurance (MALE) UAS and is an upgrade to the MQ-1 Predator UAV drone line.

The universal ground control station (UGCS) is the common control station for the U.S. Army's Shadow and Gray Eagle unmanned aircraft systems. Built on a flexible crew station architecture, the UGCS can be configured and housed based on army mission requirements, supporting a wide variety of assets and operations (Textron Systems website, 2019). In order to get a complete picture of the noise exposure of UAS operators sound measurements were conducted inside UGCS as well as around the aircraft.

Methods

Measurements were conducted around the RQ-7Bv2 Shadow and the MQ-1C Gray Eagle UAS vehicles at Fort Huachuca, AZ in July 2019. Measurements were also conducted inside of the UGCS for both vehicles. The same equipment was used for all measurements.

Unmanned Aerial Systems

Microphone placement was similar for both the Shadow and Gray Eagle UAS sound level measurements. Due to a limited opportunity to collect data, since training exercises could not be altered or interrupted, it was decided to place the microphones at varying distances perpendicular to the aircraft centerline. The height of each microphone diaphragm was 5 feet except for the microphone closest to the Gray Eagle UAS which was 4 feet high. The relative microphone positions for the Gray Eagle can be seen in Figure 4 and the first three microphones can be seen in Figure 5. The first four microphone locations at the Shadow launch site can be seen in Figure 6. The microphone distances from the aircraft centerline are shown in Table 1.

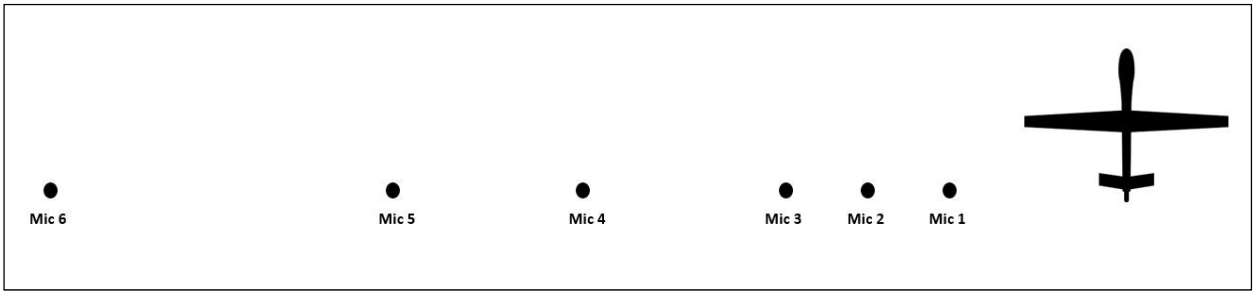

Figure 4. Microphone positions for the Gray Eagle.

Table 1. Microphone distances from the aircraft centerline in feet

Mic	Distance in Feet	
	Grey Eagle	Shadow
Mic 1	30	30
Mic 2	40	45
Mic 3	60	90
Mic 4	90	115
Mic 5	125	150
Mic 6	183	171

Prior to aircraft start up, the data acquisition modules were set up for standalone recording. This mode of operation allowed for the data to be saved as a .WAV file to a microSD card that was plugged into each module. The recording parameters were set to a sampling rate of 131,072 Hz with a frequency span of 51.2 kHz and 24-bit resolution. The data acquisition modules were powered on after all microphones were in place, but the recording was not started until the aircraft were in place and ready to be powered up.

Universal Ground Control Systems

Inside the UGCS the same six microphones and data acquisition modules that were used to measure the UAS sound levels captured the ambient sound level while the UGCS was powered on but not occupied. Figure 7 shows the dimensions and microphone layout for the Shadow UGCS. Microphone 4 and Microphone 6 were placed on the chairs to approximate crew member head positions. Figure 8 shows the front-most microphone positions in the Shadow UGCS.

Materials

Brüel & Kjær (B&K) Type 4938-A-011 (4938) microphones with Type 2670 preamplifiers (Figure 4) were used to measure sound levels. The 4938s are ¼-inch pressure-field microphones designed for high-level and high-frequency measurements. The microphones have a frequency range of 4 Hz to 70 kHz, and a dynamic measurement range of 42 dB to 172 dB with a maximum peak sound level of 180 dB(P).

Figure 11. Brüel & Kjær Type 4938-A-011 microphones with Type 2670 preamplifiers.

The microphones provided the input signal to a B&K LAN-XI Type 3050 module running Notar Time Data Recorder software in stand-alone mode. The module is a six channel system with a bandwidth of 51.2 kHz (sample rate of 131 kHz). A B&K 2270 hand-held analyzer was also used to supplement the measurement hardware. The 2270 is a multifunctional Class 1 sound measurement system the use of which added flexibility to the measurement activity. Additionally, a B&K Type 3052-A-3/0 LAN-XI data acquisition module, which has three input channels and a frequency range of direct current (DC) to 102.4 kHz, was to be used to collect additional data. Figure 5 shows the B&K Type 3052-A-3/0 LAN-XI and 2270 hand-held analyzer.

Power for the Type 3050 and Type 3052 modules was provided by Battery Module Types 2831-A. The battery module is a rechargeable Lithium (Li)-Ion battery with an output voltage of 14.8 V and a capacity of 6400 mAh. The battery is capable of powering a LAN-XI data acquisition module for over 7 hours (Brüel & Kjær, 2017).

Results

The results below are A-weighted average sound levels (LAeq) measured during the listed condition in decibels [dB(A)].

Shadow

Figure 14. Close up of Shadow on launcher.

Measurements were conducted during the launches of two Shadow UASs. The launches were separated by about 30 minutes. The results are shown in Table 2.

Table 2. Shadow UAS sound levels

dB(A)	Shadow UAS Sound Levels							
	Launch 1				Launch 2			
	Start-up	Low Idle	High (Snaps)	Launch	Start-up	Low Idle	High (Snaps)	Launch
Mic 1	96.8	91.7	110	105	97	91.4	108	107
Mic 2	92.7	87.2	105	101	92.6	87.4	104	103

Discussion

In order to assess the noise exposure of the Shadow UAS operator a microphone was placed near his position, which was about 100 ft away from the launcher, as shown in Figure 16. The operator was wearing a David Clark H10 Headset which has a listed Noise Reduction Rating (NRR) of 23 dB. Unfortunately, due to a hardware malfunction no data was collected at the operator position. However, looking at the results in Table 2 for mic 3 and mic 4, which were 90 feet and 115 feet away from the launcher respectively, it can be determined that the sound levels at the operator position would reach a maximum of approximately 98 dB(A). The NRR provided by the headset should offer adequate protection for the operator, especially due to the short exposure time of the maximum sound levels which occur during snaps (engine alternating between high and low idle) and at launch.

Figure 16. Shadow operator with microphone nearby.

The Gray Eagle Operator did not wear hearing protection. For the majority of time that the Gray Eagle UAS was on the tarmac it was at low idle and the operator was standing back at least 60 feet from the aircraft. However, there was an occasion shortly after start-up that the operator had to be next to and even under the aircraft. Measurements taken at these positions with the hand-held analyzer resulted in a measurement of 87 dB(A) next to the UAS on the right side, and a measurement of 92 dB(A) underneath. The operator was not exposed to these levels for more than a few minutes but it is still recommended that some type of hearing protection be worn. Further, Section 7-13 of DA PAM 40-501 states that appropriate hearing protection must be worn

1492 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

when working with or around aircraft that produces exposure to steady state noise levels of 85 dB(A) of any duration.

The headsets worn in the UGCSs were the RACAL RA5000/1/1026 Raptor which have an NRR of 18 dB. The UGCS sound levels are shown in Table 3 and Table 5 and according to DA PAM 40-501 hearing protection would not be required since levels do not exceed 85 dB(A).

1493 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Conclusions

The purpose of this test was to determine the sound level around the Shadow and Gray Eagle UASs and inside the UGCSs. The results indicate the Shadow UAS operator should be well protected using the David Clark H10 headset. However, it is recommended that the Gray Eagle operators use some sort of hearing protection. The sound levels in both UGCSs were relatively low and the RACAL RA5000/1/1026 Raptor headsets that are currently being used will provide more than adequate hearing protection.

Abstract

Nuclear and radiological terrorism is a persistent threat to United States national security. The research and development of new technological capabilities is vital to bolstering emergency response and prevention capabilities in support of national security initiatives. This research characterized the applicable trade-space for a system of unmanned vehicles deployed for search, detection, and identification of radiological source material. Exploration included the development of a CONOPS, a functional decomposition and physical allocation, design considerations, and an analysis of feasibility and utility. The concept system comprises of a ground control station, ground vehicle, hybrid-electric multirotor, and fixed-wing vehicle with an open architecture permitting the exchange of payload components. Payload options include a Geiger-Müller detector or scintillator for large area search and a scintillator or high purity germanium semiconductor for radioisotope identification. Endurance estimates revealed that a hybrid-electric multirotor is capable of carrying a 6.8-kilogram payload for 58 minutes. Similar estimates indicated that a battery-powered fixed-wing vehicle can provide a minimum of 41 minutes of endurance with a payload mass fraction of 15% (1.36-kilogram payload), whereas a gasoline-powered vehicle with the same payload mass fraction (1.95-kilogram payload) can operate for 12 hours. Electric multirotors are limited to a maximum endurance of 20 minutes, which is insufficient for radiological search missions. The system concept proves effective to the radiological search mission and can be expanded to other mission areas through its open architecture.

Acknowledgments

I would like to express my sincere appreciation to my faculty advisor, Dr. David Jacques, for his guidance and support throughout my thesis effort. The insight, experience, and continuing flexibility is appreciated. I would also like to thank my committee members, Dr. Justin Clinton and Dr. Christopher Chini, for the support and effort they contributed. Lastly, I would like to thank my wife for her encouragement and patience throughout the research process.

TRADE-SPACE ANALYSIS OF A SMALL UNMANNED VEHICLE SYSTEM FOR RADIOLOGICAL SEARCH MISSIONS

I. Introduction

Overview

The purpose of this research is to characterize the applicable trade-space for a small unmanned vehicle system (SUVS) to conduct search, detection, and identification of radiological and nuclear materials. The system will comprise a combination of airborne and ground platforms with integrated radiation detectors to complete a radiological search mission with input from a human operator. Both the platforms and radiation detectors suitable for the platforms will be discussed to understand the limitations and feasibility of employment.

Background

Compared to chemical and biological weapons, which also fall under the weapons of mass destruction (WMD) umbrella, nuclear and radiological materials utilize more sophisticated and technical processes in order to produce quality material for use. Due to this complexity, terrorist organizations are unlikely to produce their own materials and must acquire them through illicit means. These materials are characteristically secured and monitored during production, transportation, storage, and use so that they are not compromised. However, there are also large quantities of material available on the black market due to deficient security and accountability from previous decades. Due to the numerous uses and locations of radiological and nuclear materials, the opportunity for

1514 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

these materials to fall outside of responsible control and be utilized in nuclear terrorism is a very real threat to national and international security. In order to locate and secure these materials, federal, state, local, and international partners deploy personnel, technology, and other investigative methods to detect and interdict illicit radiological and nuclear materials before being weaponized. As stated by President Trump in the 2018 National Strategy for Countering Weapons of Mass Destruction Terrorism, "as the threat of WMD terrorism continues to evolve, however, our defenses against it must evolve as well" [1].

As part of the counter-WMD mission space, it is necessary for law enforcement and military organizations to be able to detect, locate, and confirm radioactive source material within moderate to large-sized geographic areas. Intelligence gathering may provide advanced knowledge of personnel, vehicles, infrastructure, location, and intent associated with radiological materials. However, the radiological search mission is still a difficult and potentially dangerous logistical problem that is traditionally accomplished by personnel with handheld detectors. Depending on the quantity and activity of the radiological isotope as well as the delivery method of an assembled WMD, hazards exist from both the radioactive material and the weapon's delivery system. Detectors capable of confirming radiological materials must be operated and sometimes placed within short distances of source material for long periods of time to produce accurate and usable data. Radiation exposure from highly radioactive material can cause health effects or even death if too much time is spent near the material. Furthermore, explosively driven WMDs present the potential for severe injury or death if detonated near responding

1515 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

personnel. The capability to find, locate, and confirm the existence of these hazardous materials utilizing an unmanned system would be a valued asset that could mitigate these hazards to personnel.

Research and development of unmanned vehicles for radiological response began in the 1970s with the reactor meltdown at Three Mile Island, which was further expanded with the second global nuclear accident at Chernobyl in 1986 [2]. There are many sources of research that have looked at optimizing detector technologies, configurations, and software to effectively detect, locate, and map radiation strengths [3]–[8]. There are commercially available systems that utilize detector technologies to provide usable data to an operator about radiation concentrations as well as real-time video imagery [9]. These systems have only been commercially available for a matter of years, and with constantly improving hardware and software, this is an area that will continue to progress and provide a more accurate and practical product to the end user. However, there is little research looking at utilizing a system of UVs to accomplish radiological search operations. The development of this system poses unique challenges due to the differing unmanned platforms: vehicles capable of rapid search may not be capable of dwelling near a target, while vehicles capable of long dwell times generally have short mission duration and are incapable of quickly covering large geographic areas. Creating a flexible system with multiple platforms and multiple integrable detectors allows the use of one system in several configurations to accomplish a variety of detection, location, and confirmation scenarios.

1516 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Problem Statement

Several hazards endanger personnel when conducting radiological search operations. There are potential health effects from the radiation being emitted from the source material, as well as threats from enemy combatants and potential deterrent devices in contested areas. Radiation exposure should be kept as low as reasonably achievable, commonly known by the acronym ALARA [10]. The concept of the ALARA principle is to expose the minimum amount of people to the minimum amount of radiation for the minimum amount of time. The same principle can also be applied to the other inherent dangers of radiological WMD search that are posed by enemy combatants, which would be to limit time on target to minimize the risk to responding personnel. Therefore, the development of an unmanned vehicle system for radiological search could contribute to the radiological search mission by reducing hazardous exposures to personnel and minimizing the number of personnel required for search operations.

Research Objectives

As mentioned in the background, the threat of WMD terrorism is ever present and capabilities need to be continually developed and improved to counter their employment [1]. Establishing a system of UVs for the detection, location, and identification of radiological and nuclear materials can assist in this mission set and act as a force multiplier for law enforcement and military organizations. Several research objectives have been established to fully characterize the system of UVs that could be developed for radiological search operations:

1. Characterize the SUVS trade-space for radiological search missions

1517 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

2. Develop the system framework along with the system limitations, capabilities, and design considerations
3. Assess the operational feasibility and utility from a functional and scenario perspective

For the purposes of this research, a trade-space analysis frames the solution space in which a viable and feasible result may reside [11]. When considering a radiological search SUVS and the research objectives identified above, several questions arise that will assist with addressing the objectives and the concept system design. What radiological sources are of the most interest? Which detectors are suitable for finding these sources and can be incorporated on an unmanned platform? What are the operating characteristics and limitations of these detectors? What would a shared system architecture consist of in terms of similar and differing components for radiological search and detector integration?

Methodology Overview

This research is a targeted mission area analysis scoped at the feasibility and suitability of a SUVS in support of radiological search and geolocation missions. The methods include a survey of the existing state of technology for both radiological detection and unmanned vehicle capabilities, the development of a concept of operations (CONOPS), a system decomposition, and an analysis of the feasibility and utility of the proposed system.

1518 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Research Limitations

The focus for this research is limited to sealed radiological and nuclear source material search, detection, location, and confirmation. A sealed source is any radioactive material that is encased in a manner that prevents leakage or escape of the material [10]. The encasement's primary purpose is to prevent the spread of contamination during regular use or transportation of the material. Radiological sources can be found in medicine, agriculture, industry, transportation, research, construction, geology, and mining. These sources are regularly lost or stolen, which can lead to weaponization in the form of a WMD. This research is not addressing WMD-related hazards or tactics, techniques, and procedures for operating in the vicinity of suspect WMDs. Additionally, this research is not focusing on nuclear and radiological incident consequence management operations that address the spread of contamination to people and the environment [12].

Previous Work

A previous Air Force Institute of Technology (AFIT) graduate student researched various radiation detector technologies to be flown on a small autonomous unmanned air vehicle and developed algorithms to rapidly detect, locate, and identify radiation sources. Another AFIT graduate student investigated the use of employing chemical sensors on unmanned aerial systems (UAS) in a tactical environment. The research focused on developing and employing tactics, techniques, and procedures for conducting chemical, biological, radiological, and nuclear (CBRN) reconnaissance and surveillance utilizing small UAS [13]. This research was used as a starting point for this thesis.

Preview of Thesis

This thesis is written in a traditional format. Chapter II discusses terminology, existing technologies, and previous research regarding radiation detectors and unmanned platforms. Chapter III addresses the methodology used to characterize the unmanned system and radiation detection trade-spaces. The findings and results from trade-space analysis are detailed in Chapter IV. The thesis is concluded with Chapter V, which reviews the research findings and presents potential avenues for additional research.

1520 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

II. Literature Review

Chapter Overview

This chapter will cover the fundamental science of radiation detectors to better understand the different parameters that may affect design decisions for equipping an unmanned vehicle. Furthermore, current unmanned technologies will be discussed to provide background information on the current state of technology that is available through commercial sources or pre-existing government systems.

Types of Radiation

There are multiple forms of radiation that are typically categorized by charged particle emissions and uncharged radiation. Charged particle radiation includes alpha particles, beta particles, and fission fragments. Uncharged radiation includes neutrons, gamma rays, and x-rays. X-rays, alpha particles, and beta particles are typically measured for contamination monitoring or for surveying and assessing a consequence management scenario (e.g. post nuclear detonation). Gamma rays and neutrons travel orders of magnitude further than alpha or beta particles, making them better suited for initial detection and location of radiological material [14]. Within the confines of the radiological search mission space and this research, gamma rays are the primary radiation of concern.

Gamma rays are photons with energies typically in the kilo- and mega-electron volt (keV, MeV) range. These photons are typically emitted when an excited nuclei transitions to a lower energy level, with the gamma energy determined by the differential

1521 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

of the excited and ground states of the nucleus. Many radioisotope decay events, such as alpha particle emission or nuclear fission, produce subsequent gamma photons in order to maintain nuclear stability [14].

Radiological Sources of Concern

There are over one thousand isotopes that have been found or created on earth, with the large majority being radioactive. Of the hundreds of radioactive isotopes, the International Atomic Energy Agency (IAEA) developed a list of isotopes that have hazardous direct human health effects when exposed to a sufficient quantity of said isotopes over a period of time. Using this list, the US Nuclear Regulatory Commission (NRC), working with the Department of Energy (DOE) and other agencies, established a list of 16 radionuclides of concern that, if gathered in significant quantities based on radioactivity (measured in Terabecquerels or Curies), carry the greatest risk of being incorporated into a radiological dispersal device (RDD) by terrorists (Table 1). The 16 threat isotopes can be found in most developed countries and are commonly used in research, medical, and industrial applications [15].

Categories of Radiological and Nuclear WMDs

In the realm of WMDs, there are a few types that encompass the radiological and nuclear category, which are radiological dispersal devices (RDD), radiological exposure devices (RED), and improvised nuclear devices (IND). INDs are different from RDDs and REDs in that they use fissile materials, such as Uranium-235 or Plutonium-239, in order to create a nuclear yield through a nuclear fission chain reaction. They can either be an illicit nuclear weapon that is bought, stolen, or obtained from a nuclear state, or is fabricated by a terrorist group using illegally obtained fissile nuclear material. The

1523 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

nuclear explosion from an IND releases intense amounts of energy through shockwaves, heat, prompt radiation emission, and radioactive fission fragments (also known as radioactive fallout). INDs are not the focus of this research, as they present unique challenges for detecting, but it is important to understand the differences between INDs, REDs, and RDDs. REDs utilize highly radioactive materials to irradiate some arbitrary area without physically disbursing the radioisotopes [17]. An example of a RED is a gamma ray source, such as Cobalt-60, that is taped to the underside of a public bus seat. This would expose all passengers within a certain area with potentially harmful doses of gamma radiation while remaining inconspicuous. RDDs also utilize highly radioactive materials, but actively disburse them using delivery systems such as explosives, pressurized containers, fans, sprayers, crop dusters, or building ventilation systems. Compared to REDs, RDDs can potentially contaminate very large areas with extremely small pieces of radioactive material [17]. The resultant cleanup and decontamination are a serious and challenging problem for emergency first responders, which stresses the importance of detecting and locating illicit source material before a WMD can be constructed and employed.

Gamma Interactions

In order to locate and identify gamma photons from the radioisotopes discussed previously, we need to understand how they will interact with materials in the environment as well as our detectors. There are two primary mechanisms by which this occurs; photoelectric absorption (PE) and Compton scattering (CS). In PE absorption, a gamma photon is absorbed by an atomic electron that is then ejected from one of the

1524 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

atom's electron shells. This electron then deposits its energy in the material; if this interaction occurs in a radiation detector, it can produce a signal (voltage, current, etc.) that is proportional to the energy of the incident photon. Similarly, CS occurs when a gamma ray collides with an atomic electron; in this event, the gamma ray transfers a portion of its energy to the electron and scatters in a different direction from its incident trajectory. As with a PE electron, the recoiled electron will traverse the material where the interaction occurred and deposit its energy, possibly producing an output signal in our radiation detector [14].

Gamma Spectroscopy

Once the gamma photons interact with our detector and produce measurable signals, a histogram can be produced that correlates said signals to incident gamma energies. The measured gamma energies are grouped into energy bins, typically quantified in kiloelectron volts (keV). The height of an energy bin represents the number of counted interactions that correspond to the energy bin. Across the measured energy spectrum, the histogram of energy bins and corresponding counts represents a wave-shaped line called a pulse height spectrum. The clarity of a pulse height spectrum varies and is characterized by the detector resolution, which is a measure of the detector's ability to differentiate the signals produced by gamma interactions. The full width at half maximum (FWHM) is the width of the gamma ray peak at half of the highest point on the peak distribution. Detector resolution is the FWHM divided by the energy of this peak gamma ray and is conventionally expressed as a percentage. The lower the detector resolution percentage, the more defined a spectral line is, resulting in a higher likelihood

1525 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

to identify radioisotopes. Detector resolution is affected by the detector technology, the algorithms associated with the detector software, and varies with the energy of the incident gamma ray [14]. An example pulse height spectrum delineated into energy bins and counted events is shown in Figure 1. It is important to understand how a detector's resolution impacts the accuracy of identifying the radioisotopes that are present.

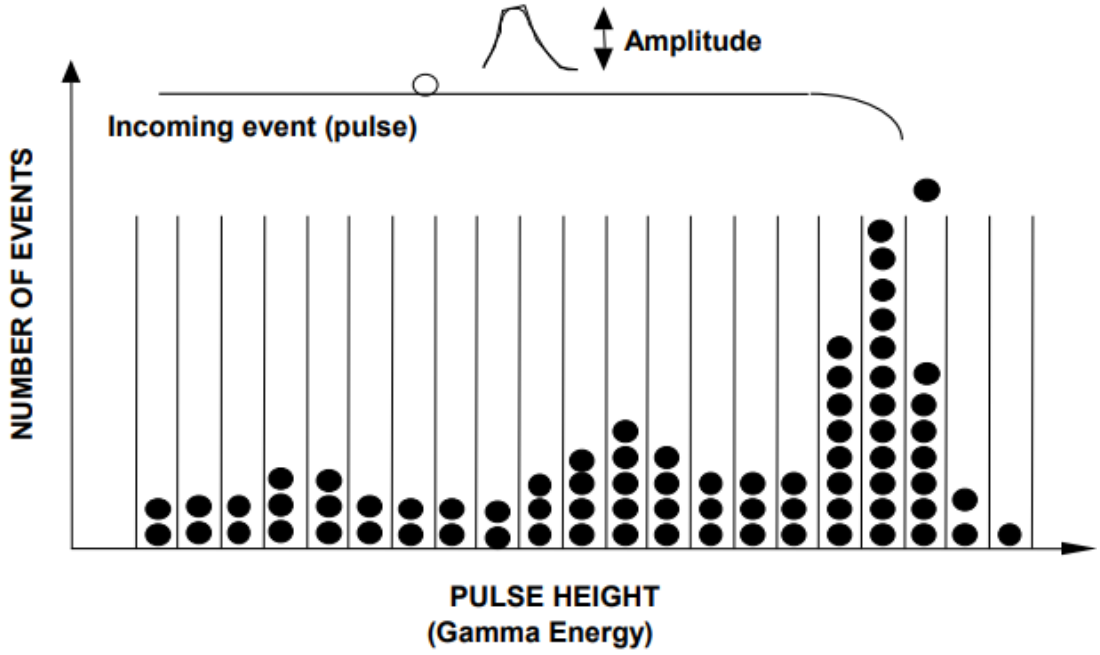

Figure 1. Voltage pulses collected into energy bins [18]

High-resolution (low percentage) detectors are more likely to differentiate between measured energy bins, allowing a more accurate assessment of which isotopes may be present. Low-resolution (high percentage) detectors may struggle to differentiate gamma photons that have similar energies, as they may be lumped together into a single energy bin. The precision of different detector technologies can be seen in Table 2. Energy

1526 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

resolutions of different radionuclide identification devices (RID) gamma ray detector types and Figure 2.

Table 2. Energy resolutions of different radionuclide identification devices (RID) gamma ray detector types [19]

Detector Type	Resolution at 662 keV
Thallium-doped Sodium Iodide (NaI(Tl))	6 - 8%
Lanthanum Bromide ($LaBr_3$)	2 - 4%
Cadmium Zinc Telluride (CZT)	1 - 2%
High Purity Germanium (HPGe)	< 0.2%

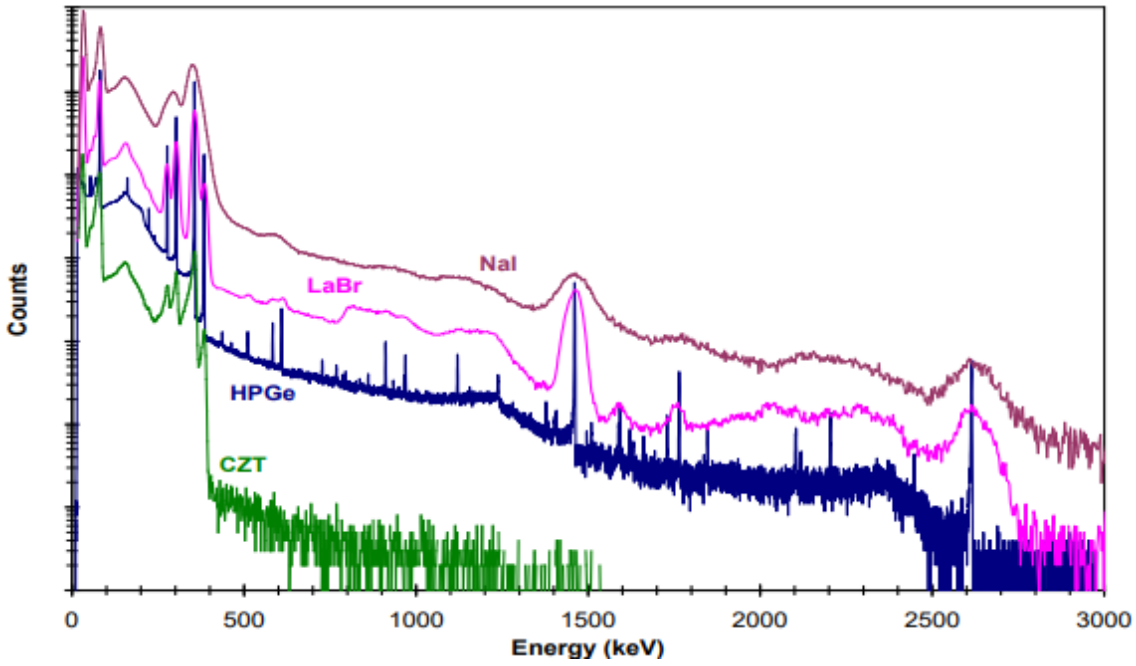

Figure 2. Barium-133 gamma ray spectra acquired with various RIDs [19]

Low-resolution detector materials, such as NaI, can lead to energy measurements blurring together into one energy peak, which does not accurately represent the energy spectrum and can lead to the misidentification of a radioisotope or a false negative. This blurring

1527 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

of NaI spectra can be seen in Figure 2 in the 300 keV to 400 keV range when compared to the other detector technologies. Furthermore, to attain the resolution of 7% listed in Table 2, the NaI detector measurement has a FWHM of about 47 keV from a 662 keV incident gamma ray. On the other hand, high-resolution detectors (e.g. high purity germanium) can differentiate between gamma energies that are within a few keV of each other [19]. In order to achieve a resolution of 0.2% listed in Table 2, the HPGe detector measurement has a FWHM of about 1.5 keV at 662 keV.

Detection Efficiency

A competing characteristic to detector resolution is efficiency; there are two components that make up detection efficiency, geometric and intrinsic. The geometric efficiency is determined primarily by a detector's distance from the radiation source and, to a lesser degree, the size of the detector. If we make the reasonable assumption that our gamma source is emitting photons isotropically, and that the size of the detector is small compared to the distance between it and the source, the fraction of emitted photons that will reach the detector (ε_G) is inversely proportional to the square of the separation distance (r^2) (Equation 1) [14].

$$\boldsymbol{\varepsilon_G \propto \frac{1}{r^2}} \tag{1}$$

If there is little to no material for the gammas to interact with between the source and the detector, this relationship can inform operational parameters such as standoff distance and loiter time.

1528 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

In contrast, intrinsic efficiency is a function of the detector itself, and is determined by the interaction material, its volume, and the energy of the incident photon. Dense materials, such as scintillators and semiconductors discussed later, have a higher concentration of electrons per volume for photons to interact with compared to gaseous material. All other parameters being equal, e.g. charge collection or conversion efficiency, a detector with a low-density material will need a larger volume than one with a higher density, affecting operational parameters such as vehicle size and carry capacity [14], [18].

Gamma Attenuation

Gamma attenuation is when a certain quantity of gamma rays passes through an intervening material. This is due to the previously mentioned PE and CS interactions that occur. Attenuation can have a large effect on the amount and strength of gamma energies incident on a detector volume. When intervening material is present, the quantity of incident gamma rays is decreased and Equation 1 no longer applies; such intervening material, such as building walls or radiation shielding, would require a detector to be closer for detection and identification.

Gas-Filled Detectors

Gas-filled detectors operate when incident radiation interacts with fill gas to create ionizations. Using an applied voltage across a cathode and anode, ions are collected to create an electrical signal in the form of a current or pulse [20]. Gas-filled detector volumes are typically sealed and pressurized in order to preserve the

1529 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

performance of the fill gas [21]. The output signal of a gas-filled detector is dependent on the voltage applied, which is pictured in Figure 3. The higher the applied voltage, the higher the output signal. Gas-filled detectors for radiation surveying are typically operated in three regions: ionization, proportional, and Geiger-Müller (G-M). Due to the low voltage of the ionization region, there is no amplification of the number of ions created by incident radiation, resulting in a detector measurement that is directly proportional to the number of original ion pairs created. The proportional region has a higher-applied voltage and operates similarly to the ionization region, except that the original ion pairs are amplified, creating more ionizations in the detector volume. The measurement of the resulting pulse is proportional to the number of original ion pairs formed. The G-M region has the highest usable operating voltage. This significant voltage difference leads to an avalanche effect following gamma interactions, increasing the produced ions by up to one million-fold throughout the entire detector volume [22].

Gas is not dense and has a low probability for interaction with incident radiation. Therefore, a larger gas-filled volume increases the probability for interaction. Additionally, operating gas-filled detectors in the G-M region increases the potential for ion pairs to be attracted to the charged electrodes, making it ideal for large area searches. Operation in this region gives the most sensitive detection capability but requires the addition of a separate power supply in order to meet voltage requirements.

1530 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

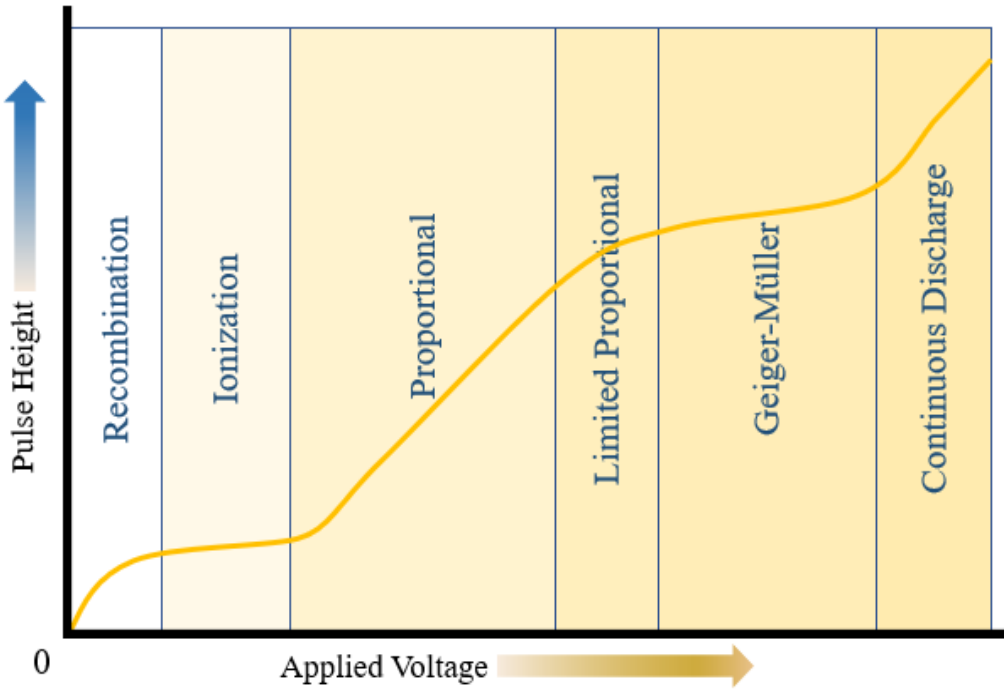

Figure 3. Gas-filled detector six region curve for gamma interactions [22]

The extra batteries, along with the necessity to increase detector volume, increases weight and space requirements and adds heat to the system. A negative aspect of gas-filled detectors is the inability to differentiate between different radiation energies. However, this is a capability that scintillators and semiconductors possess.

Scintillation Detectors

Scintillation is when radiation interacts with certain detector media and produces visual light. Scintillators can be organic or inorganic and can be a liquid, solid, or gas, but solid materials are the most common for detectors. They are typically encased in reflective materials to provide extra rigidity, waterproofing, and to prevent luminesced

1531 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

light from escaping [20]. A photomultiplier tube or photodiode converts the light into an electrical pulse that can be interpreted by detector software [14].

Each scintillation material has different inherent properties that need to be considered for detector selection, such as hygroscopicity, decay time, and sensitivity to shock. Some materials degrade if exposed to water, even water vapor in ambient air, so airtight chambers are required for certain scintillators. Additionally, scintillators are typically dense crystals that require photomultiplier tubes to convert light into meaningful data. This adds weight and space requirements that need to be considered for UV application. However, scintillators require significantly lower applied potential compared to gas-filled detectors, so a separate power supply is not necessary for operation. Vibrations can also be of concern for some scintillating materials. Depending on the scintillator, vibrations can induce counts in the materials and can damage brittle crystals, which could produce false positives and unreliable data if using for search operations [3], [23].

Plastic scintillators are low-cost, robust, and can be made very large. However, the detectors lack resolution and are ineffective for identification of a radioisotope. NaI scintillators are very common and have been employed for decades. NaI crystals can be made large (in excess of 10 centimeters x 10 centimeters x 46 centimeters) but are considerably more expensive than plastic scintillators. The advantage of sodium iodide is that it can be applied to both initial search and identification of source material. Handheld versions may be undersized for UV purposes, but a larger crystal could give

1532 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

better detection efficiency while maintaining spectroscopic abilities for isotope identification [4].

Semiconductor Detectors

Semiconductor detectors do not luminesce when interacting with gamma rays. The process is similar to gas-filled detectors, which measure resulting ionizations from radiation interactions over a voltage difference [14]. However, semiconductor detectors differ from scintillators and gas-filled detectors in that they directly measure excited electrons, which produces much better energy resolution [22]. HPGe detectors are commonly used for the detection and identification of radioisotopes due to their excellent resolution. The disadvantages of these systems are that they must be cryogenically cooled with liquid nitrogen or an electromechanical Stirling-cycle cooler, resulting in a very heavy instrument. Additionally, HPGe detectors are significantly more expensive than scintillators. An example system is the Ortec Micro-Detective. This is a 15-pound (6.8-kilogram) handheld detector that utilizes an electromechanically cooled HPGe crystal. It is capable of producing a resolution of less than one percent and can operate for 5 hours on a rechargeable Lithium-ion battery. However, the detector performance can be affected by vibration and heat [4].

Multirotor Unmanned Aerial Vehicles

Current commercially available multirotor systems use either electric power plants using lithium polymer batteries or hybrid-electric systems that utilize gas engines as generators to produce power for electrically driven motors. Electrically driven

1533 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

systems have limited operational flight times due to the low energy density of battery technology. Electric multirotor systems with sensors other than small cameras are typically limited to 30-minute duration flights, which is not ideal for conducting radiological search operations. On the other hand, hybrid-electric systems have had success in more robust and longer duration applications due to the higher energy density that gasoline provides as an energy source [24]. Gasoline-powered generators allow hybrid-electric multirotor vehicles to fly much longer and farther than their all-electric counterparts. Commercially available hybrid-electric systems currently on the market list specifications that are vast improvements upon battery powered systems. Claims of 5-hour flight duration, payloads as heavy as 12 pounds (5.5 kilograms), and a range of 110 miles (177 kilometers) are a few examples from Skyfront's Perimeter-8 model [25]. The longer duration, range, and heavier payload capabilities make multirotor systems much more attractive and applicable to arenas such as emergency response and military operations [24]. However, gasoline engines present unique design and operating issues that do not affect battery-powered systems, such as mechanical noise, combustion noise, engine start-up, generator maintenance, exhaust, cooling, and vibrations. These additional side effects of a hybrid-electric power plant could affect the overall performance of the system and the feasibility of deploying and operating in constrained environments.

Fixed-wing Unmanned Aerial Vehicles

The purpose of a fixed-wing vehicle within this system would be to cover a large area during initial the search for radiological material. In order to increase the likelihood

1534 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

for successful detection, the vehicle should operate at lower altitudes to have the highest probability of radiation interaction with the on-board radiological detection system. Additionally, time over target is also an issue due to detector hardware and software delays. A fast platform may not detect radiological material during overflight compared to a slower moving platform. Therefore, a balance between speed and endurance must be managed in order to adequately meet desired performance outcomes. Fixed-wing platforms have been around longer than multirotor systems and can vary greatly in size and in the type of power plant. Hand-thrown battery-powered platforms have been operated in many restrictive and rural environments but are limited by the payload weight and area that can be covered. Incorporating liquid fuel engines to drive single propellers has proven successful for platforms over 20 pounds (9.1 kilograms). An example of small UAS capabilities is the UAV Factory Penguin series. It is available as a battery-powered system or with an electronic fuel-injected engine, with claims such as endurance from 110 minutes to 20 hours, range of up to 60 miles (97 kilometers), and a payload upwards of 22 pounds (10 kilograms). Early models of the system have been flown since 2009 and are utilized in more than 43 countries [26].

Unmanned Ground Vehicles

Unmanned ground vehicles were some of the earliest operated unmanned mobile systems. They were utilized as early as 1981 during the Chernobyl nuclear reactor meltdown in the attempt to limit exposure to responding personnel [2]. Many variants and sizes are currently operated by federal and local governments across the United States and internationally. Ground vehicles have the advantage of being able to loiter in

1535 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

an area for long periods of time and also carry the heaviest payloads compared to aerial vehicles. However, ground vehicles are limited in range and can be disabled by rough terrain and obstructions.

1536 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

III. Methodology

Chapter Overview

The purpose of this chapter is to discuss the methods used for analyzing multiple focus areas of the radiological search mission. The resulting research will culminate in characterizing the trade-space for the unmanned vehicle system. Methods to be used include a concept of operations, a system decomposition, and a feasibility analysis of utilizing the system for radiological search operations and other mission areas. The flow of this research will resemble the highlighted portion of the systems engineering "V", which is depicted on the left side of Figure 4.

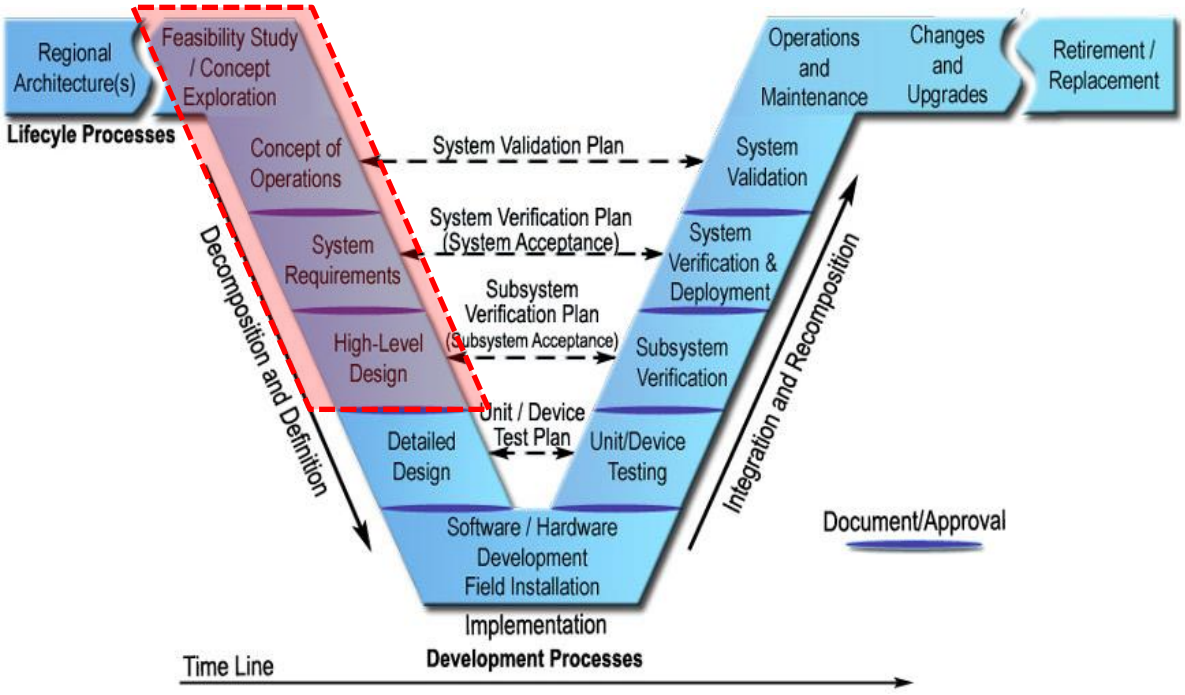

Figure 4. Systems engineering "V" for system development [27]

1537 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

A CONOPS for the system will be established with corresponding measures of effectiveness (MOEs) at the mission level. The CONOPS is not linked to user requirements, but rather a hypothetical approach to unmanned vehicles for completing radiological search missions currently accomplished with human operators. Use cases will be derived from the CONOPS, as well as resulting tasks, attributes and measures of performance (MOPs). A system decomposition of the functional system architecture with functional tasks and a physical hierarchy will be derived in order to allocate system functions to componentry. The approaches to these methods will be further discussed below.

Concept of Operations

An assessment of radiological search operations will be conducted in order to determine the realistic operational umbrella that an unmanned system could be deployed in support of. Understanding the limitations of the mission space that the system is applicable to will also apply to the derivation of the system's architectural makeup as well as potential architecture modifications needed to make the system useful in other mission areas. Within the overarching mission of performing radiological search, it is important to understand what limitations there are by introducing unmanned platforms and what information needs to be collected and delivered by an unmanned system. A CONOPS will be established which will detail mission needs, limitations, capabilities, and scenarios appropriate to the system. Additionally, it will include the tasks, attributes, and measures of the conceptualized system [28].

1538 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The CONOPS will also include a mission timeframe, operational needs, system limitations, enabling capabilities for system operation, and valid scenarios for system employment. The system CONOPS will frame the mission set that it can be deployed in support of. An example CONOPS from the 2019 AFIT UAS three-course design and testing series will be used as a baseline for this research. In addition, some imposed design requirements of the system will be presumed and discussed in terms of their functionality to the mission and why they are important for operational use.

Mission needs will provide information about expected capabilities the system should have to perform the radiological search mission. These can be made for both friendly and adversarial conditions and will be logical, realistic, and necessary for continuing the conceptualization process. Unrealistic assumptions will be avoided, with the focus being placed on gaps in knowledge that are important for successful planning and characterization of the system. Operational limitations can be physical in nature or be due to self-imposed policy that restricts operational functionality. Policy can be leadership driven, multinational, or economic based. Operational constraints can be imposed in the form of rules of engagement, which can vary between commands, organizations, and political boundaries. Policy concerns will not be discussed in this research, with the focus being placed on physical operational limitations of the various subsystems of the unmanned system. Environmental and scenario-specific constraints will be addressed as part of the physical limitations.

Lastly, scenario examples will be provided in order to understand the range of missions that the conceptualized system can cover. These scenarios define friendly and

1539 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

adversarial conditions, enabling capabilities for system functionality, and the expected value toward mission completion. The scenarios used in this research are not all-encompassing of the system's abilities but provide context to the potential utility of the system.

System Decomposition

Using the CONOPS, a decomposition of the system will be derived. The decomposition will consist of a use case model for the system, a functional decomposition, and an allocation of system functions to physical componentry. The CONOPS will drive the contents of the functional decomposition. The CONOPS will have traceability to the functional decomposition and the physical architecture of each system module. At the basic level, physical componentry of the various systems will be linked to performing all tasks associated with completing the radiological search mission.

The functional decomposition and allocation will be completed using Cameo System Modeler 19.0, which is a model-based systems engineering software tool that uses Systems Modeling Language (SysML) to develop systems engineering solutions [29]. As a starting point for the functional decomposition and allocation, a reference architecture will be used and expanded upon. The reference architecture (RA) was developed by several AFIT professors associated with the small unmanned aerial system courses [30]. The RA is organized by four top-level packages, which comprise a component library, a basic multirotor system, a basic ground control station (GCS), and an example system concept integrating the GCS and fixed-wing UV. Components within each package are further broken down into value properties and ports that characterize

1540 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the component, such as memory capacity, operating system type, radio frequency, and cost. The properties are customizable for the user's desired specificity, but not comprehensive of everything that may need to be measured. Additional properties can be added to the concept system's componentry blocks as needed. Lastly, the RA provides an example of a decomposed CONOPS for a remote targeting system with a use case model and the associated activity diagrams. The user of the RA is responsible for developing a use case model and functional tasks that meet the requirements for the pertinent CONOPS with traceability to physical componentry, which is the end state of the system decomposition for this research.

Using the established use cases, tasks, attributes, measures, as well as MOEs, MOPs, and performance factors will be derived that exemplify mission execution of the use cases [31]. Mission-level tasks that feed into mission execution will be identified along with important attributes that are valuable and feasible to measure. These tasks, attributes, and measures are evaluating the mission space from an agnostic perspective, pertaining to both human and system execution. An MOE is a measure of how well an operational task or set of tasks is executed within its expected operational environment. MOEs will be established that pertain to the radiological search mission and the expected operating environmental conditions yet are mission-based and not system-specific [32]. MOPs are a refinement of MOEs and provide measurable performance factors that help evaluate an MOE's status. The attributes will coincide with MOPs and the attributes' measures will be analogous to listed performance parameters. The list will not be exhaustive of all potential MOEs, MOPs, and performance parameters, but will highlight

1541 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

key factors that characterize the system's effectiveness at completing the radiological search mission.

Analysis of Feasibility and Utility

The last segment of this research is to evaluate the feasibility of incorporating the system into radiological search operations. The spectrum of mission operations will be considered, to include execution of the entire operation with an unmanned system, incorporating the system into a portion of operations, or not utilizing the system for radiological search missions. However, the focus of the feasibility discussion will be the scenarios identified in the CONOPS. As part of the feasibility analysis, estimates of vehicle endurance will be determined corresponding to vehicle size, battery and fuel capacity, and payload size. Furthermore, the system's utility to other mission areas will be assessed, along with the necessary system architecture modifications to expand its capabilities for current and emerging missions.

1542 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

IV. Analysis and Results

Chapter Overview

From the methodology presented in Chapter III, the analysis of the radiological search system will be approached from an academic yet practical perspective. Characterizing the system, its capabilities, and the physical framework to meet those capabilities are beneficial for gaining an accurate sight picture of the conceptualized system. However, the academic approach will culminate with the feasibility analysis of the system by realistically considering the potential benefits and possible drawbacks that this system could present to gaining units and agencies for the radiological search mission and other mission areas. New technological capabilities are not always viable to replace or supplement current tactics, techniques, and procedures, which will be discussed at the end of this chapter.

Concept of Operations

This CONOPS defines a prototype system and the associated efforts to assess system architecture and demonstrate the feasibility and utility of a concept solution before a prototype demonstration phase. The CONOPS, and the proposed system framework solutions associated with it, address the system's vehicles, sensors, user interface software, communication system, support functions, and operator actions for application to the radiological search mission.

1543 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Scope

This CONOPS is intended to be an enabling concept and is written at the tactical level. More specifically, the radiological search CONOPS describes the projected utilization by Department of Defense (DoD) CBRN personnel, explosive ordnance disposal (EOD) technicians, and special operations forces (SOF), as well as analogous federal, state, and local entities necessitating the capability to detect, locate and confirm the existence of hazardous radiological material. The radiological sources will be in one of two categories: an orphan source where the material is lost or stolen or when the material has already been weaponized into an RDD or RED.

Mission Timeframe

Mission timeframe refers to the expected time it will take to research, develop, acquire, test, and deploy the objective system to operational units. The intent for the system's research and development phase is to utilize commercial off the shelf (COTS) and government off the shelf (GOTS) technologies to reduce initial startup time typically seen for newly developed systems. Applying previously researched and tested equipment to system construction will expedite this portion of the process. It will also shorten the time required to develop training programs and support equipment required to field the system. The mission timeframe is expected to be between two and five years. Two years is a best-case estimate to allow for research, acquisition, testing of the separate components, and assembling them into an operative system of systems. This also includes the procurement of support equipment and the development and execution of training for system operation and maintenance. The system should be completed and fielded within

1544 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

five years due to the rapid pace of innovation in the unmanned vehicle industry. A system under development for a longer period of time will be outpaced and become obsolete prior to becoming operationally fielded.

Mission Needs

The system will deploy to meet intelligence-based missions as required or to aid in the search and recovery of lost, stolen, or other forms of radiological source material. The system under consideration should be small in size but capable of searching an area of 3 square kilometers or larger, to include, but not be limited to, large urban buildings and sea-based vessels. The system is to be used by tactically deployable units from federal, state, and local organizations, so logistical requirements should be moderately small in size. The system should function with no more than four human operators and should be deployable utilizing no more than a transport vehicle and trailer for transportation. The objective system should be easily maintainable and should integrate as many COTS and GOTS components as possible. Garrison maintenance equipment capabilities and battery charging units are within the scope of the objective system. This does not include commonly found tools such as wrenches and screw drivers. While the unmanned vehicles are intended to be reusable, the cost of the systems should be sufficiently low to allow disposal in lieu of costly decontamination, hazardous recovery, and vehicle loss or theft. Due to the potential operation in contested areas, loss or theft of system vehicles should not provide substantial exploitable information or materiel to adversarial forces.

1545 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The baseline system shall contain a combination of air vehicles, a ground vehicle, and a ground control station for user interface. Using the system of vehicles equipped with various and interchangeable payloads, the system will be able to locate and confirm the existence of radiological source material, as well as generate a three-dimensional radiation dose rate contour map of the search area. Due to the continuous improvement of technology in unmanned vehicles and radiation detection equipment, the system shall employ a modular, open system architecture which facilitates the integration of new sensors and subsystems throughout its lifecycle. This includes but is not limited to defense programs of record (PORs), COTS and GOTS technologies, and sensors associated with other CBRN constituents. However, the system should make extensive use of COTS and GOTS componentry and existing vehicles in order to minimize development time and system cost. The objective system's air vehicles shall adhere to DoD UAS Group 1, Group 2, or small Group 3 weight, altitude, and speed requirements for low altitude maneuverability and tactical deployability (Table 3).

Lastly, the system will allow for semi-autonomous operation with real-time, human-in-the-loop control. Each operational task will require a certain level of human input, which necessitates a varying degree of control given to the GCS or on-board processor. The level of autonomy will be driven by the risk of each task and the impact it has on mission completion. The overall level of autonomy is relatively low, with most tasks requiring operator input or pre-planned tasks for the system to execute. Consequentially, the shared responsibility between a human operator and the system GCS

will range from #1 to #4 across the Taxonomy of the Distribution of Responsibility between Human and Computer (Figure 5).

1547 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

1. Human does all planning, scheduling, optimizing, etc. and turns task over to computer merely for deterministic execution.
2. Computer provides options but the human chooses between them, plans the operations, and then turns task over to computer for execution.
3. Computer helps to determine options, and suggests one for use, which human may or may not accept before turning task over to computer for execution.
4. Computer selects option and plans action, which human may or may not approve, computer can reuse options suggested by human.
5. Computer selects action and carries it out if human approves.
6. Computer selects options, plans, and actions and displays them in time for human to intervene and then carries them out in default if there is no human input.
7. Computer does entire task and informs human of what it has done.
8. Computer does entire task and informs human only if requested.
9. Computer does entire task and informs human if it believes the latter needs to know.
10. Computer performs entire task autonomously, ignoring the human supervisor who must completely trust the computer in all aspects of decision making.

Figure 5. Taxonomy of the distribution of responsibility between human and computer [34]

Enabling Capabilities

Some capabilities fall outside of the radiological search SUVS scope but are necessary to enable the system's effective use. While the system may make use of on-board navigation sensors for terrain avoidance, it is anticipated that the system will utilize the global navigation satellite system (GNSS) for maneuvering to waypoints, tracking its position, and mapping radiation strength of the search area. Low cost alternative navigation (non-GNSS) technologies are emerging but may not be available for deployment in the two to five-year window envisioned for this system. The system should be transportable by a light to medium-duty truck with a trailer or a small

1548 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

waterborne vessel for deploying the system to the operational area of concern. The transport vehicle should be capable of powering the GCS and associated GCS-operated equipment, as well as charging vehicle batteries when forward deployed. However, external power may be required when forward deployed for multiple missions or long durations.

Scenarios

The listed scenarios are broad and cover the entirety of mission phases that need to be accomplished by the system. The scenarios not only pertain to the conceptualized system, but also entail inherent interactions and inputs from the human operators of the system. The envisioned phases of system operation include ground control setup and teardown, vehicle deployment, mission execution, and system recovery.

Ground Control Setup & Teardown Phase

This phase encompasses all actions necessary to deploy the SUVS including unpacking, inventory, assembly, function checks, mission planning, disassembly, and reconstitution. Since the system is intended for use with forward deployable units, transportation of the system must be compatible with deployed vehicles or small waterborne vessels. The system must be capable of operating without externally supplied power. A system built-in-test will signal to the operator if the system is fully operational; if the system is not 100% operational, the built-in-test will identify all system faults. Mission planning for the system should be practicable prior to deployment, prior to beginning operations when on site, and modifiable during on-going operations once vehicles have been launched.

1549 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Vehicle Deployment Phase

This phase encompasses all actions necessary to achieve initial vehicle movement starting from a properly configured vehicle or vehicles and a ground control station. No more than two operators should be required to deploy a vehicle. Following built-in-tests, mission plans should be wirelessly uploaded to involved vehicles prior to launch. The vehicle deployment phase ends once movement toward the target area is achieved and the system begins waypoint navigation.

Mission Phase

This phase includes a variety of tasks as defined by the selected payloads and established mission plan. It is envisioned that the system will be capable of waypoint navigation to both pre-planned and ad-hoc waypoints, can loiter or hover depending on the vehicle type, can navigate terrain, and can operate attached sensors at designated waypoints per the mission requirements. Mission tasks that should be accomplished in order to meet the desired capabilities of the system include:

1. Loiter or hover about a waypoint or navigate to a sequence of waypoints while providing real-time radiological strength measurements to the ground control station. Video imagery from search should be recorded and displayed to the ground control station in real-time. Video options will be available for both daytime and low-light conditions, with enough quality for the ground control station operator to detect human figures based on the displayed imagery. The operator will designate a target search area with the ground control station software and the system will

1550 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

search the designated target area based on vehicle telemetry, with a desired accuracy of 15 meters distance root mean squared (DRMS). The initial search should yield calculated location(s) of radiological source material based upon maximum radiation readings and telemetry data. The system should be capable of displaying a radiological strength contour map of the target area to the ground control station operator.

2. Navigate to a waypoint and hover, land, or dwell at the location while providing real-time video imagery to the ground control station. Video imagery should be recorded and displayed to the ground control station in real-time. The operator will designate the target location(s) calculated from the initial area search. Once at a designated target location, the system will confirm the detected radiological sources by collecting a gamma spectrum of the source material. Spectrum data will be provided to the ground control station and the system will predict the radioisotopes based off the measured gamma energies.

3. Traverse the exterior wall faces of an urban structure, covering both the horizontal and vertical extent of a building. The system should employ terrain avoidance while maintaining a safe distance from a structure in order to avoid damage to or loss of a vehicle. The desired location accuracy of 15 meters DRMS is driven by the need to avoid collateral damage in urban environments. While traversing the exterior wall faces of a building, the system will record radiation strength measurements at

1551 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

locations adjacent to the walls. These radiation measurements will be used to develop a three-dimensional contour map to pinpoint probable locations for the source material.

4. Perform a commanded ditch or crash maneuver in the event of system faults or circumstances making recovery impossible or undesirable, such as unavoidable contact with hostile personnel or compromise of the system. Each system vehicle will encompass a self-destruct module to make the system unusable if seized by unfriendly forces.
5. Perform a return to launch (RTL) at any time during operation. An RTL will return the vehicle to a pre-programmed location where it will perform the recovery phase.

Recovery Phase

This phase involves recovering the vehicles upon completion of the mission or as deemed necessary. The UVs should be capable of navigating to a recovery location designated by the ground control station operator. Unassisted takeoff and landing of air vehicles are desirable if done safely and to ensure rapid recovery and reuse of the vehicle. Batteries must be replaceable in the field and additional fuel should be available for sequential search or continuing large area search or surveillance operations.

System Decomposition

Use Cases

A use case model for the system has been developed using Cameo Systems Modeler to visualize the main operational functions that the system needs to perform, as

1552 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

well as the interactions the system has with actors, external systems, and the environment (Figure 6). The use cases are based on mission needs, enabling capabilities, and scenarios previously mentioned. The entire system is responsible for performing setup, planning the mission, deploying and ingress, performing search and confirmation activities, egressing and recovery, and self-destruction if necessary. Several use cases require interactions with the GNSS, the physical environment, and human operators,

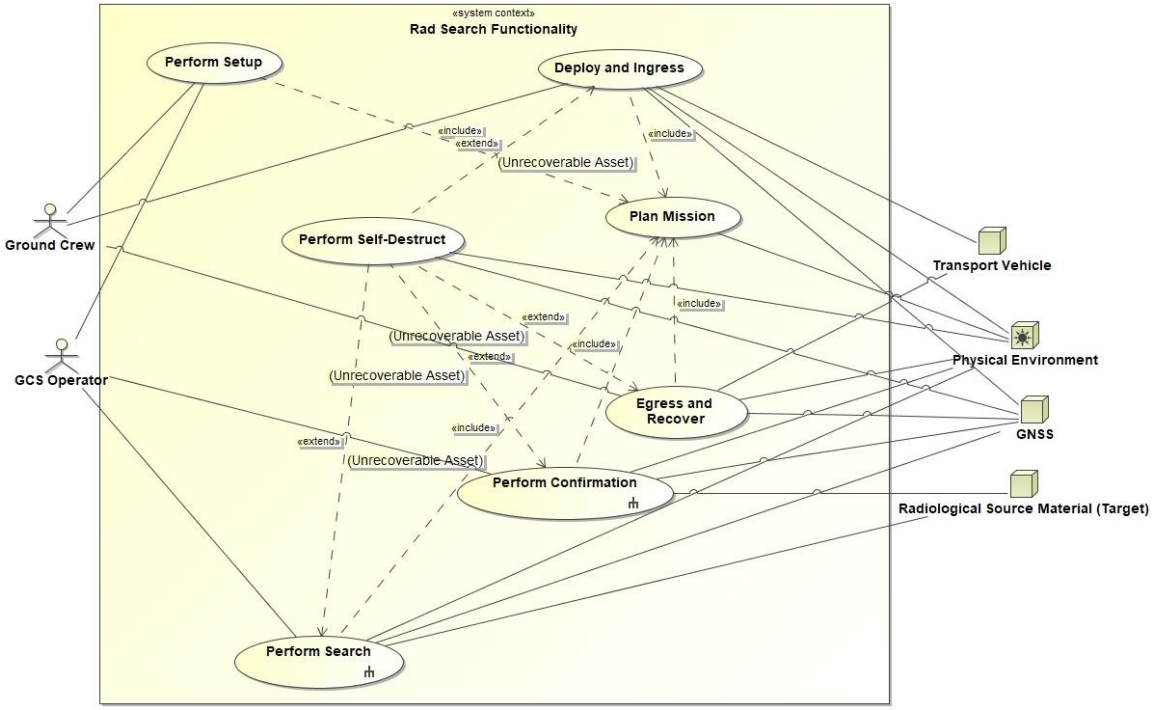

Figure 6. Use case model for the radiological search system

whereas the target radiological source material only relates to performing search and confirmation. The use cases holistically provide the necessary functions to execute the entire spectrum of the radiological search mission, as determined by the CONOPS. The details of the individual use cases can be found in Appendix B.

1553 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Tasks, Attributes, and Measures

Within the confines of the radiological search mission, there are basic tasks that must be accomplished as part of mission execution. The tasks, along with the associated attributes and measures, can be seen in Table 4. This list highlights important variables

Table 4. Mission-level key tasks, attributes, and measures

Task	Attribute	Measure
Search	Coverage	Duration [min]
		Total area searched [m^2]
		Area coverage rate [m^2/s]
Detect	Accurate	Probability of detection [%]
		False alarm rate [alarms/mission]
Navigate	Accurate	DRMS absolute location error [m]
		DRMS relative location error [m]
Communicate	Secure	Encrypted/not encrypted
	Range	Range [m]
Confirm	Spectral resolution	Resolution [% FWHM]
	Source position accuracy	DRMS location error [m]
Mission-wide	Workload	Minimum crew size required [# personnel]
	Availability	Mission turn time [min]
		Mission ready rate [% mission capable]

that apply to the mission. The tasks are essential for executing the individual use cases, and therefore meeting the intent established in the CONOPS. The attributes and measures capture what can be considered significant measurable data for task evaluation if system development were to occur. It should be noted that the list does not encompass all tasks that need to be performed nor all measures that should be considered for evaluation. Additionally, there are some attributes and measures that apply across all mission tasks, which are combined in a "mission-wide" task category. The major tasks

1554 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

for mission completion are search, detection, navigation, communication, and confirmation. The established mission-level tasks feed MOEs for the radiological search mission and the expected operating environmental conditions [32]. From there, system-specific MOPs were developed including measurable performance factors for evaluating the MOEs. The MOPs are related to the task attributes and the attributes' measures correspond to performance parameters. The list of developed MOEs, MOPs, and performance parameters are in Table 5. As mentioned previously, the MOEs, MOPs, and performance parameters are not exhaustive and provide an academic assessment of critical data that should be measured to assess system performance against mission execution.

Table 5. MOEs with system-specific MOPs and performance parameters

MOE	MOP	Performance Parameters
Success rate of locating and identifying radiological source material in a 3 square kilometer search area	Location accuracy of radiological source(s)	Detector dead time [ms]
		Detector dose rate range [mSv]
		DRMS relative location error [m]
		DRMS absolute location error [m]
	Confirmation accuracy of radiological isotope(s)	Spectrum resolution [%]
		Minimum energy detected [keV]
		Maximum energy detected [keV]
	Endurance	Weight [kg]
		Power capacity [W]
	Area coverage rate	Camera FOV [°]
		Operating altitude [m]
		Vehicle cruise speed [m/s]
	Degree of autonomy	Autonomy scale [Figure 5]
	Video imagery resolution	Ground sample distance [m]
Ability to communicate data to a remote-control point across a 3-kilometer distance	Data processing speed	GCS processing speed [GHz]
		Data transmission rate [Mbps]
	Data encryption	Y/N
	Transmission range	Tx power [dB]
		Rx power [dB]

Functional Decomposition and Physical Allocation

Continuing with the system hierarchy, the functional decomposition and allocation of physical componentry can be produced. For the purposes of this research, the CONOPS identified system requirements are based on assumptions and personal knowledge of the radiological search mission space. This is unlike traditional processes where requirements are identified by operational users of a conceptualized system [28]. The requirements as presented herein are traceable to the use cases, tasks, attributes, measures, and now to the functional decomposition and physical architecture of the system. Individual tasks are essential for the completion of the different scenarios mentioned in the CONOPS as well as for the execution of each use case. A conglomeration of all derived tasks for a vehicle and the GCS can be seen in Table 6.

Table 6. Derived system tasks between vehicle and GCS

Vehicle Activities		GCS Activities	
Auto land	Load MP	Analyze spectrum data	Display video
Auto takeoff	Loiter	Calculate target coord	Receive MP status
Capture video	Navigate waypoints	Combine rad data/telemetry	Receive rad data
Collect rad data	Send rad data	Connect to vehicle	Receive spectrum data
Collect rad spectrum	Send spectrum data	Construct MP	Receive telemetry
Conduct BIT	Send telemetry	Create rad map	Send cmd
Follow search pattern	Send video	Display rad data	Store rad data
Initiate search	Trigger self-destruct	Display rad map	Store spectrum data
		Display rad spectrum	Store target coord
		Display radionuclide	Store telemetry
		Display target coord	Store video
		Display telemetry	Write MP

The functional decomposition has been split at the system level into vehicle activities and GCS activities, represented in the MBSE format in Figure 7. For this research, the vehicle activities generally apply to and cover all activities for the ground, fixed-wing,

1556 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

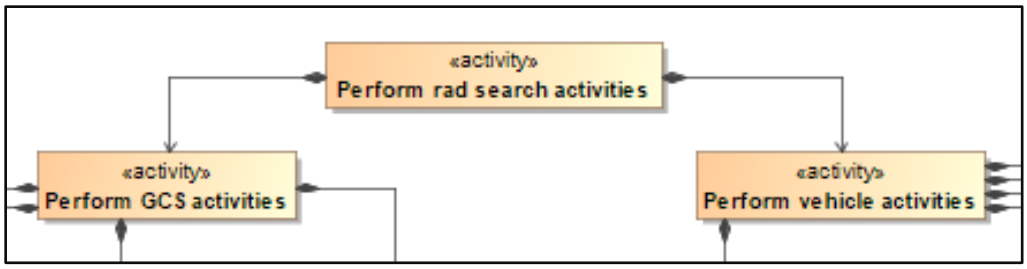

Figure 7. System functional decomposition

and multirotor UVs. The activities for the various vehicles are broken down into performing controlled movement, autopilot function, vehicle data communications, radiation measurement, and providing video (Figure 8).

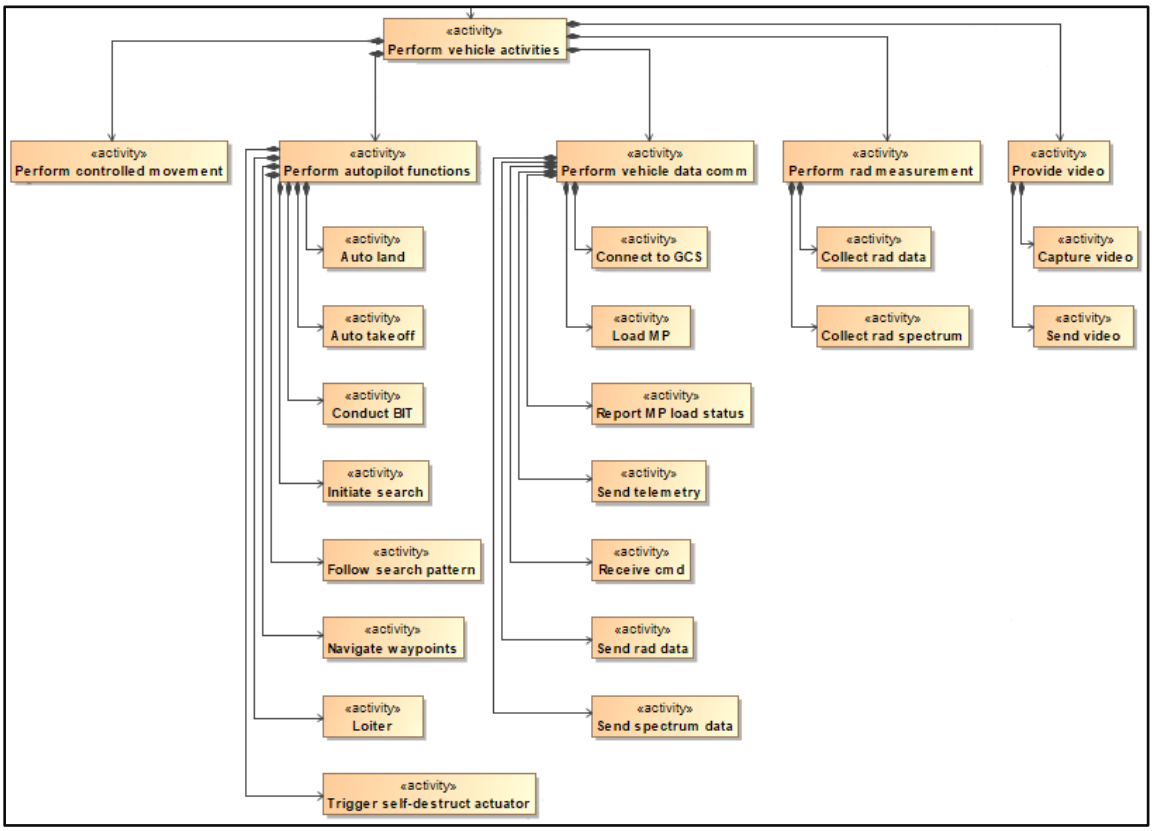

Figure 8. Generic vehicle functional decomposition

1557 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

For the ground control station, the functional decomposition is categorized by processing, providing data communication with system vehicles, providing interface and output for the GCS operator, and receiving video from vehicles. The GCS sends commands to system vehicles, receives and displays video, and receives, processes, and displays critical flight and radiation measurement data (Figure 9).

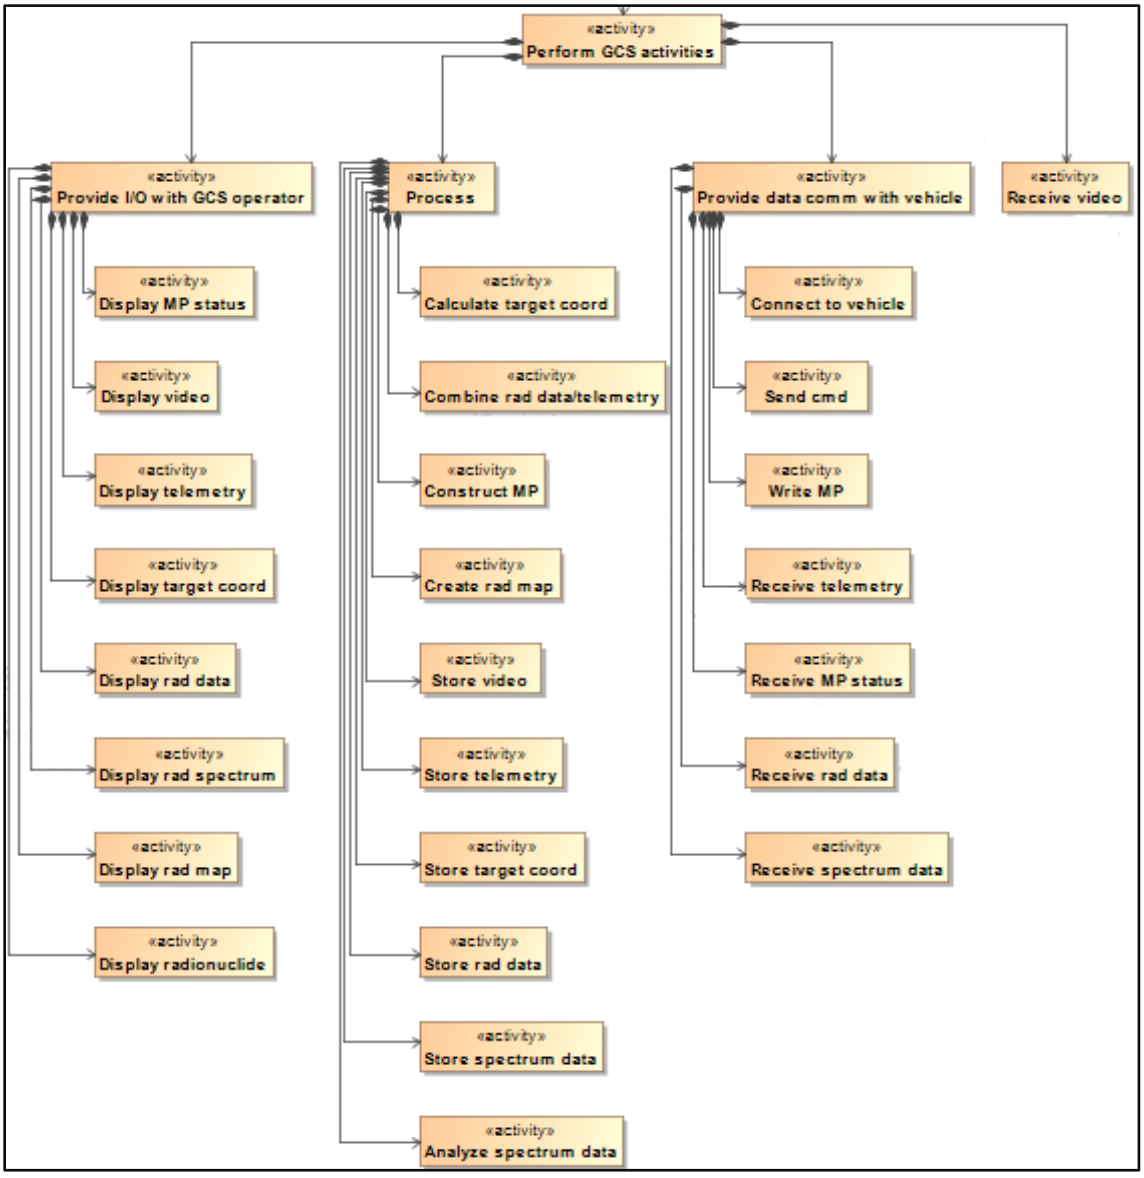

Figure 9. GCS functional decomposition

1558 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The physical architecture consists of singular components, organized into system modules, that fulfill the execution of tasks listed in the vehicle and GCS functional decompositions (Figure 10-13). The vehicle modules are navigation, payload, power, self-destruct, and the vehicle itself. The subsystem breakdowns are not exhaustive lists

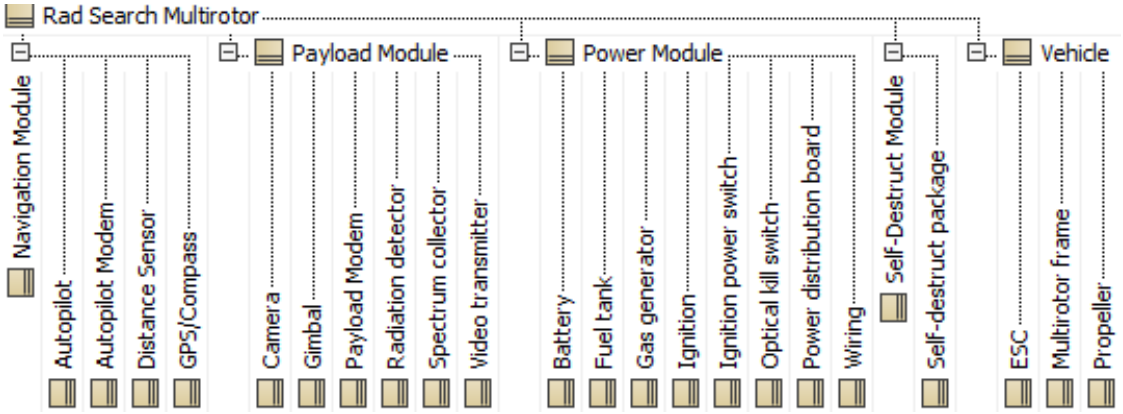

Figure 10. Multirotor physical architecture

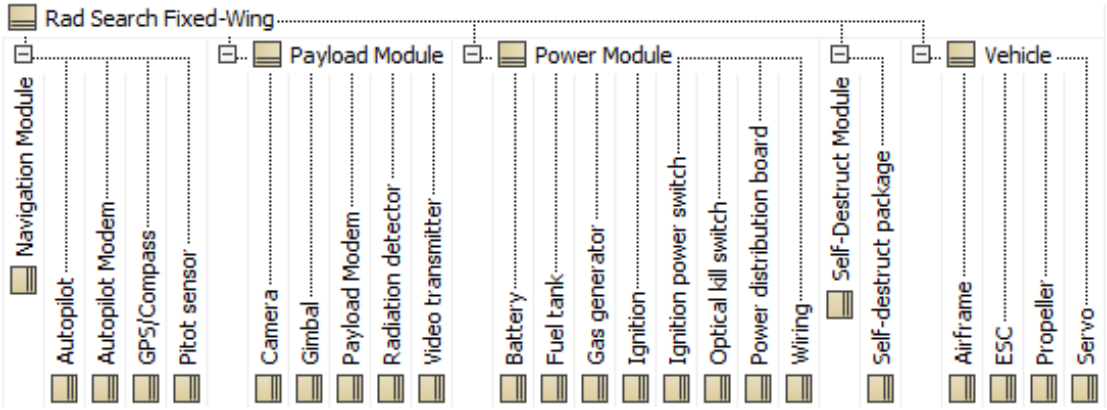

Figure 11. Fixed-wing physical architecture

1559 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

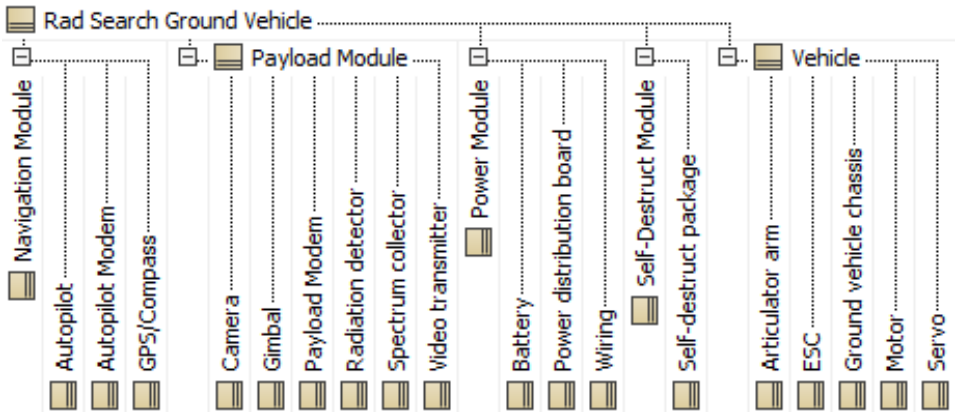

Figure 12. Ground vehicle physical architecture

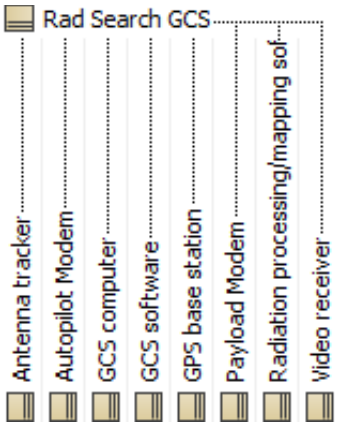

Figure 13. Ground control station physical architecture

of all physical hardware but include major components that should be considered for future design and sizing. It should be noted that the power modules for the multirotor and fixed-wing vehicles contain both batteries and gasoline-based engines, which will be discussed later in Chapter IV. Additionally, there is no power system listed for the ground control station, as this will be powered by the transport vehicle used to deploy the system and human operators.

1560 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

From the different physical architectures, the subsystem components can be allocated against all system tasks from the functional decomposition. Allocating each individual task against each component within the system continues the traceability from the CONOPS, to the use cases, to the tasks, and lastly to the physical hierarchy of the system. An allocation of each activity to a subsystem component satisfies this traceability (Table 7). Each activity that is necessary for mission completion is being satisfied by at least one component or one subsystem module. The individual vehicle and GCS physical allocation matrices can be found at Appendix A. By categorizing the subsystems, the physical components, and the executable tasks, a simplified analysis for potential hardware redundancy is possible.

Design Considerations

There are several avenues for system design based on the established CONOPS and system decomposition. These include similar and dissimilar componentry as well as factors that could attribute to certain design decisions such as payload type, processing capabilities, and the operating environment. In order to evaluate the system componentry, the three vehicle systems and the ground control station were assessed. A comparison of subsystem components and their equivalent to other systems is shown in Table 8, identifying hardware that can use similar components, hardware that is similar but likely use different components, and hardware that is dissimilar.

Similar Componentry

After a rudimentary comparison, it is evident that there are multiple overlapping components in the payload, navigation, and power modules, as well as the self-destruct package. Due to the assumed simplicity of the system concept and maximizing existing COTS and GOTS hardware, equivalent components should be selected in order to duplicate the capability of each component within the overarching system. This creates redundancy throughout the system, enabling the cannibalization of one vehicle system in order to make another system fully operational. For instance, similar modem components should be incorporated for transmitting telemetry data, payload data, and video stream. Redundant hardware facilitates the interchange of system components with little to no re-programming if operational constraints arise. This can be crucial to operators if they are limited on spare parts or if geographically separated from the main operating location by providing the ability to troubleshoot a subsystem when hardware becomes inoperable.

1564 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The decision to swap components from one system to another is driven by mission and scenario need. For example, intelligence identifies a single building as the target location for a radiological source. This would not require the use of a fixed-wing UV since a large area search is not needed. The components of the fixed-wing UV can be cannibalized in order to ensure mission execution with the other two system vehicles. On the contrary, a large area search requires a fixed-wing UV for initial detection of the radiological material. However, the fixed-wing UV can be disassembled after initial detection is complete, the search area has been narrowed, and when follow-on search and identification can be managed by the multirotor or ground vehicle. Hardware redundancy provides the flexibility to prioritize and execute mission needs when necessary.

Hardware Variations

There are also multiple componentry differences amongst the vehicle systems and the ground control station. Modules with major variations from other systems include power production, the ground control station, and the vehicle itself. As is anticipated, the vehicle chassis will be dissimilar for the various UVs. This includes the vehicle propulsion system, which consists of the motors (electric and gasoline-fueled), servos, propellers, and wheel tracks. The last distinctive vehicle component is an articulator arm on the ground vehicle, which can be used for object manipulation and as an extra mounting point for vehicle payloads.

In order to meet the system's intent of searching large areas as well as carrying payloads in excess of 15 pounds (6.8 kilograms), the power plants for the different vehicles cannot be restricted to battery-powered systems. Other options to be considered

1565 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

include small combustion engines and hybrid-electric motors. The fixed-wing vehicle is required to accomplish an initial search to localize where radiological material is located, with the potential to continue operations as a surveillance asset. Due to the potential for long-duration flights, this capability is best supported using a combustion engine in lieu of batteries to drive the propeller. A gasoline engine will enable flight times of several hours and increases the required size of the vehicle, which is beneficial for payload capacity. Battery-powered fixed-wing vehicles can achieve flight durations over 1 hour but will not be able to carry equivalent payload weights with comparable endurance times to gasoline-powered systems. Comparatively, a battery-powered multirotor system would not have the endurance to cover all potential source locations within a 3 square kilometer area for collection of a gamma spectrum. A hybrid-electric system would provide greater endurance and offers an increased payload capacity compared to battery-powered multirotor vehicles. Battery-powered systems of the desired sizing are typically limited to 30-minute flight times, which is insufficient for carrying detector payloads to the farthest sites of a large search area. Additionally, batteries can take 30 minutes to an hour for recharging if spare batteries are unavailable, which can hamper the ability to execute consecutive sorties. Endurance estimates supporting the above discussion can be found later in Chapter IV. Opting for fuel-based power systems is ideal for providing longer endurance due to a higher energy density compared to battery technology, which can be visualized in Figure 14. Utilizing liquid fuels for the fixed-wing and multirotor UVs will increase flight durations, area coverage, and maximum allowable payload, optimizing performance of these systems and providing optionality for other uses such

1566 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

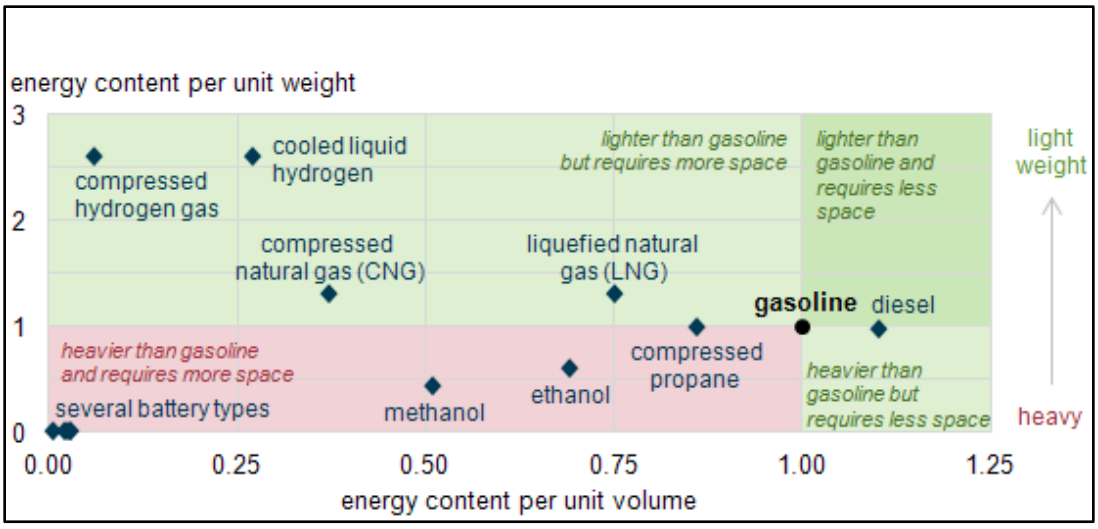

Figure 14. Energy density comparison of several transportation fuels (indexed to gasoline = 1) [35]

as surveillance missions.

In addition to the detector payloads, additional payloads should be included on vehicles to assist with navigation and surveillance. Light detection and ranging (LiDAR) or other distance measuring sensors should be incorporated on the multirotor to provide accurate navigation when flying around buildings and other potential obstacles. This will provide more accurate radiation measurements and enhanced safety by decreasing the likelihood that a collision occurs. Additionally, the fixed-wing UV could benefit from a higher quality video camera compared to cameras installed on the other vehicles. The fixed-wing's optionality to provide aerial surveillance would benefit from high-quality video and would better support ground operators.

Physical Limitations and Imposed Design

System components are constrained to the mission needs listed in the CONOPS and limited to the operational requirements of the mission area. Two important

1567 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

limitations to highlight are the restrictions on system mass and the extended endurance required to cover a 3 square kilometer search area. The two limitations drive the sizing of each subsystem vehicle, their power plants, and the quantity of vehicles utilized in the system. A minimum of three unmanned vehicles (fixed-wing, multirotor, and ground), a ground control station, and the accompanying storage, power, communications, and maintenance equipment must be containable in a truck and trailer for system deployment. Additionally, due to the nature of radiation emissions discussed in Chapter II, detector payloads are more likely to detect gamma radiations when closer to the radiological source material. This negates the viability of using large unmanned vehicles that operate at higher altitudes such as the RQ-1 Predator and MQ-9 Reaper that are categorized as DoD UAS Group 4 and Group 5 systems (Table 3).

On-board processing has been removed from the conceptualized design in the physical architecture. This capability requires additional vehicle power and produces unwanted heat, which would reduce mission endurance and could present overheating issues in warmer operating environments. Additionally, an on-board processor introduces the risk of leaking sensitive information regarding system software and vulnerabilities to adversarial forces if captured or ditched in a contested area. This will be discussed in more detail later in Chapter IV.

Power

As discussed previously, power production can be an issue for the fixed-wing and multirotor platforms. This is dependent on payload selection for the system and the required flight endurance for the individual vehicles. A liquid-fuel engine for the fixed-

1568 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

wing would increase the size of the vehicle but would greatly improve the endurance and the payload capacity. Similarly, a hybrid-electric motor for the multirotor would have a comparable effect. However, using combustion engines would increase the complexity of the system regarding mechanical components and potential maintenance. Furthermore, a deployable system may be constrained by available types of fuel. DoD Directive 4180.01 promotes the use of multiple energy sources for weapon systems and equipment, where appropriate, and becoming operational with one battlefield fuel [36]. Typical small combustion engines used on fixed-wing and multirotor vehicles consume 91 octane fuel or higher [25]. Expeditionary vehicles, aerospace generation equipment, and power generation assets are typically fueled with diesel or jet propellant-8 (JP-8). Expanding the capabilities of the system to utilize heavy fuels, if combustion engines are chosen for power generation, would provide more options for system deployment and would reduce vulnerabilities if 91 octane fuel is unavailable. Small two-stroke gasoline engines (10 cm^3 to 100 cm^3) have been proven to run on heavy fuels with minimal degradation to peak performance power. However, this required engine modifications such as replacing carburetors with throttle body fuel injection systems and changing stock engine control units to adjustable ignition timing maps [37].

In addition to meeting endurance and payload capacity, adequate power needs to be generated or supplied on-board in order to power video cameras, navigation systems, and payloads. The largest payload consumer of power would be gas-filled detectors and semiconductor detectors, which operate at higher voltages. With this being the case, it is advisable to power these detectors with separate power supplies. Utilizing separate

1569 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

power supplies for all detector payloads would enable optionality for handheld use and would reduce the complexity and drain on the vehicle's power system. It is possible to power these systems, but this also increases the size of the combustion engine and the vehicle frame to support the engine. A good example is the Airborg H8 10K Hybrid UAS. It claims a flight endurance of 1 hour carrying a 22-pound (10-kilogram) payload, with a power output of 100 watts and built-in 5 voltage direct current (VDC) and 12 VDC wiring. The longest dimension of the vehicle is 6.4 feet (1.95 meters) and the total weight with a 22-pound payload is 110 pounds (50 kilograms) [38]. This would be sufficient voltage for the Ortec Micro-Detective, which requires 10 to 17 VDC for operation [19].

Environmental

The operating environment of this system is important to understand since operations will primarily be outside. Many common components used for unmanned vehicles are designed for use in -20° to 50° Celsius temperatures, but some components, such as the Ortec Micro-Detective, may have a smaller temperature window for operation [19], [25], [26], [39]. Other components that may be affected are batteries and circuit boards. Extreme cold weather can reduce the overall power output of a battery, whereas extreme heat can lead to physical damage. On-board processing equipment such as autopilot systems and detector payloads can also be affected by hot weather, causing damage to circuity and decreased performance. Desired operating temperatures for the system could affect component selection and design for each vehicle.

1570 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

In addition to temperature constraints, other weather constraints could affect the operational utility of the system. Visual capabilities could be limited by fog, precipitation, smog, and sunlight. Unless night vision video cameras or other imaging solutions are utilized, night operations would be dangerous or not viable. Additionally, precipitation may affect system functions, either from individual component waterproofing or physical limitations of vehicle propulsion. Lastly, flying vehicles must maintain stable flight while airborne. Strong steady and gusting winds would limit the use of flying vehicles, with the wind limits being better defined during system design.

The last environmental concern is from obstacles and human interference. The operating area may contain trees and buildings that could impede flying operations, or uneven terrain such as ditches and rocks for a ground vehicle. Design considerations should be made to mitigate these risks, such as the addition of specific payloads to see and avoid terrain or the ability to traverse uneven ground with the addition of extendable wheels or tracks. Additionally, the human element can interrupt vehicle operations. Threats can be in the form of thrown rocks, nets, vehicle theft, small arms fire, or man-portable air defense systems. There are few design decisions that can currently mitigate these threats, but technology is continuously progressing and the capability to avoid human threats may present itself in the future.

Detector Payload

In order to optimize the performance of the radiological search system, detectors for initial detection and spectrum collection should be evaluated separately. It is valid to employ multiple detector technologies due to the diversity of radiological search

1571 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

scenarios. Detector selection can vary due to several reasons: 1) detector selection can be driven by the type of area to be searched; 2) detector selection can be dictated by the size of area to be searched; 3) detector selection is limited by the vehicle it will be deployed on; and 4) detector selection can be determined by the desired mission outcome.

Gas-filled detectors are well suited for area surveying during initial searches. More specifically, the higher applied voltage in G-M detectors results in a sensitive detector, which is ideal for large area searches that may require detection from long distances [14]. Additionally, typical COTS G-M detectors have higher radiation dose rate thresholds. The high threshold enables G-M detectors to avoid detector saturation when in strong radiation fields, and therefore continue to function and provide radiation strength readings [19]. This results in a more defined geolocation of source material after the initial search. However, G-M detectors do not measure the energy of incident gamma rays, which can be important for determining health and safety concerns for responding personnel.

Scintillators can also be used for area searches but tend to have lower radiation dose rate thresholds [19]. This translates to detector saturation in strong radiation fields where G-M detectors could still be operating, resulting in a less accurate geolocation than G-M technologies. However, both scintillators and semiconductors are well suited for gamma spectrum collection because they can distinguish between different energies of incident gamma rays, allowing for the identification of radioisotopes. Scintillators are cheap and lightweight but produce low resolution spectrums. On the contrary, semiconductors are expensive and heavy due to the required cooling systems that

1572 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

maintain low operating temperatures but provide very high-resolution spectrums [21]. Equipping the system with multiple technologies gives the capability for high-resolution spectrums, but the optionality to use the less expensive and lighter scintillator in unfavorable conditions.

The vehicle type can determine payload selection. For instance, a spectrum collection payload is not ideal for deploying on a fixed-wing vehicle. Spectrum collection should be completed at a constant distance from a radioisotope and in a stable position. A fixed-wing vehicle is unable to maintain a constant distance during flight but is well-suited for searching large areas when the location of source material is unknown. The optimal payload for a fixed-wing vehicle is a G-M detector due to its sensitivity, but scintillators are also a practical option. Terrain and environmental conditions can force a fixed-wing UV to fly over one hundred meters AGL, making higher-sensitivity detectors more desirable for initial detection. For isotope identification, the current government "gold standard" for gamma spectroscopy is a liquid or electromechanically cooled high purity germanium crystal [40]. This setup provides a superior resolution spectrum compared to existing scintillator technology but may not be feasible on a multirotor or ground vehicle due to weight limitations and the operating environment.

The physical and immediate surroundings of each vehicle should also be assessed. The two main considerations for detector mounting are material interactions and susceptibility to impact. Interactions with other vehicle materials can include vibration-induced gamma counts, gamma counts produced from other on-board electronic equipment, and self-imposed shielding. Unintentional shielding can happen when an

1573 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

intervening material from a vehicle is between the detector media and the radiological source. The intervening material can weaken or alter the gamma energies incident on the detector, ultimately decreasing the potential for initial detection and degrading the accuracy of spectrum collection [19]. Similarly, shielding material may need to be utilized between the detector and other electronic hardware in order to reduce false gamma readings that occur from other types of electromagnetic radiation. The other physical consideration is the potential for detector impact. Collision with obstacles, human interactions, and harsh landings can affect detector performance and can dictate payload attachment and hardening design. Depending on the detector and the vehicle, attachment options can be limited due to size and weight. Vehicle center of gravity constraints and chassis strength will drive mounting options to ensure that vehicles safely fly and maneuver as designed. Detector hardening may also be limited due to vehicle payload capacity but should be evaluated during system design.

One last consideration for payload selection is the additional capability for the detectors to be used in a handheld configuration by the system's human operators. Situations may present themselves where the initial search, the spectrum collection, or both methods are not appropriate for unmanned vehicles. Terrain, environmental conditions, and other on-scene factors can differ from provided intelligence. Once an operational team arrives at the search location, it may be logical to modify the mission plan to conduct a portion of or the entire mission using personnel search teams. Depending on their equipping, they may need the capability to conduct searches with the same equipment deployed on the UV system. Commonly used GOTS and COTS

1574 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

handheld detectors can vary in price from $1,000 to $100,000, which is contingent on the type of technology purchased [39]. It may be more cost effective to include handheld-operable equipment in the system. This would limit the overall detector acquisition cost to the end user, avoiding the need for redundant technologies that are dedicated to either a UV system or a human operator. If handheld detectors are employed, it is essential that the detector's human interface can be bypassed in order to send data and receive commands. A commonly used COTS semiconductor detector designed for handheld use is the Ortec Micro-Detective. As previously mentioned, it utilizes an HPGe crystal to provide a spectral resolution of less than one percent. The purchase price for this equipment is upwards of $100,000 but provides the highest-quality gamma spectrum compared to other spectrum-collection technologies. With a weight of 15 pounds (6.8 kilograms), this equipment is only suitable for the ground UV and for short-duration trips with a large multirotor [19]. However, including this piece of equipment also enables the human operator to collect a high-resolution spectrum if the mission dictates. Additionally, there are many COTS handheld detectors that come equipped with G-M and scintillation technology [19]. This could increase the efficiency of a mission by completing the initial search and radioisotope identification with one vehicle trip, thus avoiding payload exchange when a high-resolution spectrum is not required. This is only practical on the ground and multirotor UVs due to the constant distance required for spectrum collection. The flexibility of equipping the UV system with handheld technology increases the probability of mission success regardless of evolving or

1575 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

unforeseen circumstances. Table 1Table 9summarizes considerations for UV detector selection in order to meet operational needs.

Communication Modems & On-board Processing

As mentioned in the similar componentry assessment, comparable communication modem pairs could be used to provide redundancy and flexibility throughout the system if hardware becomes inoperable. Additionally, on-board processors have been removed from the Cameo physical decomposition to reduce power-draw, weight, heat, and to avoid sensitive data exploitation if a vehicle is lost or stolen. If vehicle on-board processors are included during system design and testing, multiple modems may not be necessary for each vehicle. However, in order to capture, combine, and encrypt multiple payload data and video feeds, a custom communication modem and processor may be required that is not available commercially or through existing government PORs.

1576 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The development of a custom communication modem and processor will depend on the established requirements, payload selection, and discoveries during the design and testing phases. The system needs the ability to communicate amongst a GCS and multiple UVs while encrypting and combining data streams, and also providing the flexibility for future payloads to be added to the system. There may not be a component that will satisfy system demands and be available commercially. Sourced payload manufacturers may not have compatible output data and could pose problems when sending or processing different data packet types and lengths. These reasons could force a requirement for on-board processing to assist with data management before communicating from a vehicle to the GCS. The on-board processor could be integrated with a communication platform that is equipped on each UV and the GCS. This could solve issues posed by data compatibility, encryption, data combination, and time synchronization. A solution for these issues would most likely necessitate a custom-designed component in order to function properly, as well as provide the flexibility to for additional payloads and other mission areas.

Processing Software

In addition to a custom-designed communication and processing package, custom software will likely need to be developed. This includes software on the GCS platform as well as software for the on-board processors. Vehicle software should be capable of combining data from various payloads and the autopilot before relaying the information to the GCS. Simultaneously, the software must decipher commands received from the GCS before relaying the commands to the appropriate vehicle components. On the

1577 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

ground, GCS software provides input and output functionality to the GCS operator. The software should be able to merge pertinent data received from a vehicle autopilot, detector payload, and video camera into one visual interface. It should have the capability to display real-time radiological data, display a three-dimensional radiological strength contour map of the search area, and provide source location estimates from the combined radiation data and telemetry data (Figure 15). Additionally, the software

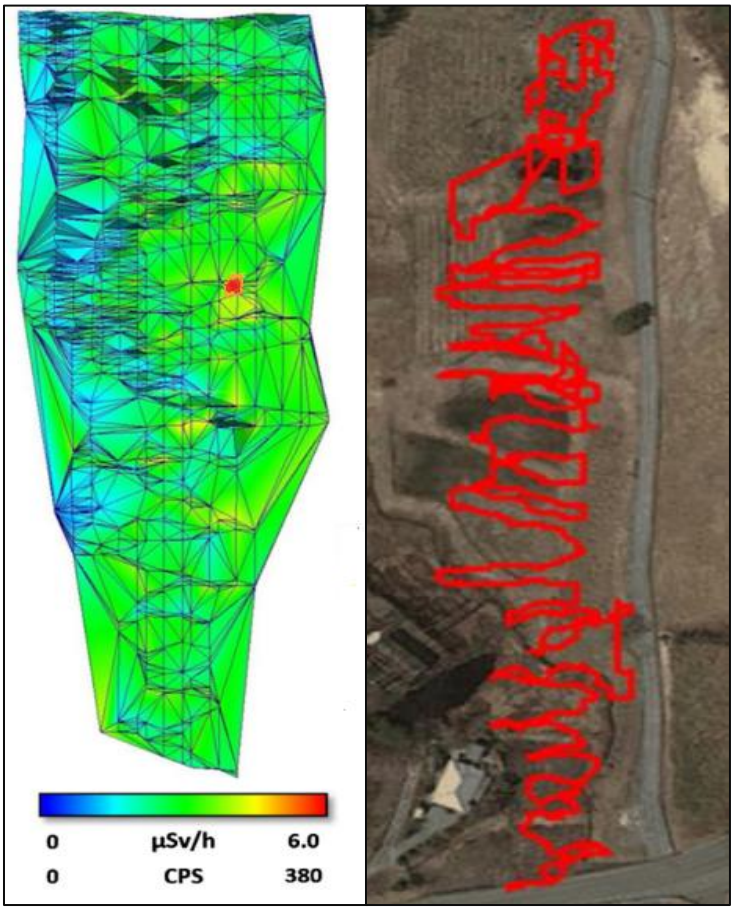

Figure 15. 3-D radiation strength map (left) of a vehicle search pattern (right) [41]

should provide real-time and planned vehicle locations on a map, similar to existing autopilot software suites. Lastly, the software should provide command options for both

1578 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

vehicle navigation and payload functions, such as starting and stopping spectrum collection, controlling camera gimbals and articulator arms, and being able to toggle between autonomous and controlled movement.

Analysis of Feasibility and Utility

After progressing through concept development, applicable scenarios, a task and physical decomposition of the system, and design considerations, the overarching query remains whether the system would be practical to employ and what utility it could provide to the radiological search mission and other mission areas. The concept system's abilities can be fundamentally evaluated through sizing and endurance estimations for multirotor and fixed-wing UVs. Ground vehicles are more forgiving with payload capacity, and therefore will not be analyzed due to the several COTS options that meet example payload requirements [42], [43], [44].

Air vehicle sizing and performance will be centered on assumptions founded upon similarly sized UAS specifications and incorporating handheld detector weights where appropriate. Assumptions are made for component sizes, efficiency ratings, air speeds, and mass fractions based on AFIT professor knowledge, existing literature, and existing COTS systems [45], [45], [46]. Mass fractions (MF) are typically tracked for vehicle payloads and for power sources (i.e. battery, fuel), and provide thresholds for vehicle estimates. The mass fractions for unmanned vehicles typically fall within the same range, with the fuel mass fraction ranging from 0.2 to 0.3 and the payload ranging from 0.1 to 0.3 [45]. Mass fractions can be estimated using Equation 2.

1579 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

$$MF_{component} = \frac{W_{component}}{W_{takeoff}} \quad (2)$$

Incorporating handheld detectors would be the worst-case scenario for payload weight and size due to the additional weight from ruggedized cases and integrated power supplies, but it also gauges the feasibility of employing handheld detectors on UV platforms. Custom-designed detectors can be a fraction of the weight but typically do not include power sources, hardening, or user interfaces for handheld operation. Example payloads will be used for multirotor sizing, whereas fixed-wing vehicles will use mass fractions and total takeoff weight to determine system endurance.

Electric Multirotor Sizing

Multirotor sizing is estimated from derived power equations related to current draw and battery capacity that can maintain the vehicle in a constant hover. The power required for each prop (P_{prop}) is dependent on vehicle mass (*m),* the area and efficiency of the prop (A_{prop}, η_{prop}), the number of motors (n_{motors}), and the density of air (ρ_{air}) (Equation 3) [45], [46].

$$P_{prop} = \frac{2 \cdot A_{prop} \cdot \rho_{air}}{\eta_{prop}} \cdot \left(\sqrt{\frac{m \cdot g}{2 \cdot A_{prop} \cdot \rho_{air} \cdot n_{motors}}} \right)^3 \quad (3)$$

The power required for each prop to maintain hover determines the current required for each motor (I_{motor}), which also depends on the battery voltage ($V_{battery}$) and the motor efficiency (η_{motor}) (Equation 4) [46].

1580 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

$$I_{motor} = \frac{P_{prop}}{V_{battery} \cdot \eta_{motor}} \quad (4)$$

The total current (I_{total}) required for vehicle operation is found using the total number of motors (n_{motors}) and additional current requirements ($I_{auxilary}$) (Equation 5) [46].

$$I_{total} = I_{motor} \cdot n_{motors} + I_{auxilary} \quad (5)$$

In order to determine the UV's endurance (E), the usable battery capacity (C_{usable}) has to be calculated by using the rated capacity of the battery (C_{rated}), the efficiency of the battery ($\eta_{battery}$), the permissible battery discharge depth (f_{usable}), and the number of batteries ($n_{batteries}$) (Equations 6-7) [46].

$$C_{usable} = C_{rated} \cdot \eta_{battery} \cdot f_{usable} \cdot n_{batteries} \quad (6)$$

$$E = \frac{C_{usable}}{I_{total}} \quad (7)$$

Sizing was calculated for electric DoD UAS Group 1 and Group 2 multirotor vehicles. The Group 1 multirotor was estimated to carry a FLIR IdentiFINDER R400-NG, which has a NaI(Tl) scintillator for dose rate measurement and radioisotope identification and a G-M tube for high radiation field dose rate equivalence. This payload adds 1.2 kilograms to the overall mass with dimensions of 24.9 centimeters × 9.4 centimeters × 7.6 centimeters and an 8-hour runtime on internal batteries [19]. A Tarot T960 hexacopter frame with Tarot 5008-340KV motors were used for mass and power estimates. Including two 10 ampere-hour 6-cell lithium polymer (LiPo) batteries to the

1581 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

system, the overall mass is 9 kilograms, which is within the threshold for Group 1 UAS. Hovering at this weight produces an overall endurance of 20 minutes. A summary of the input data and results can be found at Table 10.

Table 10. Group 1 electric multirotor endurance estimate

Payload mass [kg]	1.2

Endurance [min]	**19.6**

The Group 2 multirotor was estimated to carry an Ortec Micro-Detective-DX, which uses an HPGe semiconductor and electromechanical Stirling-cycle cooler for dose rate measurement and high-resolution identification. This payload adds 6.8 kilograms to

1582 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the overall mass with dimensions of 37.3 centimeters × 14.6 centimeters × 27.9 centimeters and a 5-hour runtime on its lithium-ion battery pack [19]. A Tarot T960 hexacopter frame with T-Motor-U7-420KV motors were used for mass and power estimates. Including three 10 ampere-hour 6-cell LiPo batteries to the system, the overall mass is 16.7 kilograms, which is 6 kilograms below the Group 3 UAS threshold. However, it should be noted that the total mass exceeds the recommended 15-kilogram design threshold for the frame [47]. This estimate, although not advisable for design purposes, provides a best-case operating endurance using the lightweight frame and heavy payload. Even with these risky operating parameters, hovering at this weight only produces an endurance of 13 minutes. A summary of the data and results can be found at Table 11.

Hybrid-electric Multirotor Sizing

Group 1 and Group 2 electric multirotors provide short endurance flights, which limits their application to cover small search areas. Therefore, an estimate was completed of a Group 2 hybrid-electric multirotor that uses a gasoline generator to charge a LiPo battery to power the motors. The gasoline provides a higher specific energy while the battery provides a simpler and more reliable method for throttling power to the six

1584 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

electric motors. The same Ortec Micro-Detective-DX payload was used, but this time a GAIA 160 Elite Pro 2.4 kilowatt hybrid-electric drone was used as a baseline system [48]. The same power equation (Equation 3) was used to determine the power required per prop, which was then totaled for the entire system. The gas generator can supply a constant 2.4 kilowatts of power at a fuel burn rate of 2.5 liters per hour. This allows for an endurance of 58 minutes when flying with 3 liters of fuel and retaining 20% of fuel at the end of mission. Results from the estimation are detailed in Table 12.

1585 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Fixed-wing Sizing

Fixed-wing sizing was completed for a Group 1 electric vehicle and a Group 2 gasoline-powered vehicle. The maximum takeoff weights ($W_{takeoff}$) for the electric and gasoline UVs are the maximum allowable for Group 1 and Group 2 vehicles, which are 9 kilograms and 25 kilograms respectively. Vehicle airspeeds (v) were varied for both vehicles so high and low endurance estimates can be compared. The lift-to-drag ratios (L/D) were also varied in order to provide endurance ranges. The endurance equation is similar to the multirotor endurance equation, but the battery power equation incorporates the takeoff weight, the vehicle air speed, the lift-to-drag ratio, and the summated propulsion efficiencies ($\eta_{propulsion}$) from the electronic speed controller, the propeller, and the motor (Equations 8-9) [45].

$$E = \frac{C_{usable} \cdot V_{battery}}{P_{battery}} \tag{8}$$

$$P_{battery} = \frac{W_{takeoff} \cdot v}{L/D \cdot \prod \eta_{propulsion}} \tag{9}$$

For the fixed-wing vehicles, specific payloads were not chosen for mass. Instead, a mass fraction of 15% of the takeoff weight was used for the allowable payload mass in order to estimate the endurance. The endurances for the Group 1 electric vehicle range from 41 to 69 minutes when flying at a constant angle of attack at the given cruise airspeeds. A summary of the estimated endurances and ranges can be seen in Table 13.

Feasibility for Current Radiological Search Operations

At a minimum, the conceptualized system would serve useful for a portion of current operations. Executing the entire operation from the initial search through completing source disposal is unlikely. This is due to the potential unfavorable scenarios and environmental conditions that could be encountered, especially when weighing the limited performance of certain vehicles such as the electric multirotor endurance and payload capacity. Incorporating the system into a portion of operations is very feasible. For instance, conducting an initial search of a large area would be extremely useful for responding personnel, especially if the terrain is difficult to navigate by foot or is not accessible by vehicle. Once the initial search area has been decreased, unmanned platforms could provide an excellent asset for surveillance by providing immediate feedback to personnel on the ground. However, confirmation activities using the unmanned system may have limited applicability. In most permissible scenarios, human operators are best suited to finish ground operations including spectrum collection and follow-on activities. Non-permissible environments may warrant the full utilization of

1588 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the radiological search system, especially when strong sources or nefarious activity and entrapments are involved. Nevertheless, utilizing the system in place of human operators is dependent on system-mitigated hazards and efficiently accomplishing the tasks expected of human teams.

When considering the estimated endurances for the vehicle power plant configurations, there are performance constraints for some vehicles and optionality for others. The fixed-wing is able to execute the mission using both electric and gasoline power plants. The endurance and payload capacity are much higher for the gasoline engine, but the overall size of the vehicle is increased. The larger size could decrease vehicle maneuverability, forcing the vehicle to fly at a higher and safer operating altitude. This is not ideal for detecting radiation. Therefore, detector sensitivity, operating altitude, and airspeed should be assessed when selecting the fixed-wing vehicle and detector payload. On the other hand, multirotor vehicles are limited to hybrid-electric setups in order to provide sufficient endurance while carrying a detector payload. This would supply enough power to ingress, collect a spectrum, and egress from any estimated source location. Battery-powered multirotors offer limited endurance and are too risky for incorporating into the radiological search system.

An important aspect of evaluating system feasibility is the cost of the system, which depends on design decisions and other factors that are not the focus of this research. Regardless of having a tangible price, the same comparison needs to be made concerning the cost of the system against the utility it provides the user. The procurement cost and recurring costs will not be worthwhile for some agencies based

1589 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

upon their scope of responsibility and the probability that they will have to respond to a lost or stolen radiological source. The typical small-town police department would not benefit from this system as both the probability of response is low and there is most likely a federal or state asset that is the principal agency for this type of emergency response. Agencies that would benefit from this system would be those responsible for large metropolitan areas, have a high-threat environment including radiological material, cover high-density areas of NRC Category 1 and Category 2 radioactive materials, and those that are deemed principal responding agencies per governing policy. State and local agencies that could realistically benefit from an unmanned search system include large metropolitan area police departments and high-volume ports. Federal applicability ties directly to existing policy and emergency response plans that define who is responsible for specific emergency scenarios and jurisdictional areas, such as the Federal Bureau of Investigation, the DOE and national laboratories, the Department of Homeland Security, and the DoD. For example, the Radiological Assistance Program (RAP) under the DOE is one of many organizations formed to assist with radiological emergency responses. The United States is split into nine geographic regions that are covered by separate RAP teams [50]. These teams could benefit from an unmanned radiological search system as part of their equipment suite to cover the array of radiological response missions they are responsible for.

The last issue that this system would introduce is logistical requirements on the owning organization. Like the initial procurement cost of the system, the cost for maintenance and replacement parts should be measured against the utility of the system.

1590 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Maintenance issues can be time consuming and costly, which depends on the complexity of the system and the necessity to procure specialty tools or equipment. If maintenance is completed by the owning organization, maintenance hours on this system would decrease hours spent on other serviced equipment and potentially impact other mission areas. Increased manpower or dedicated maintenance technicians may be necessary, which also increases the overall cost. If a separate maintenance contract is determined to be the optimal route, this requires continual funding to ensure the system maintains operational readiness. The aforementioned costs will help decision-makers determine the realistic acquisition and implementation of this system.

Utility to Other Missions

It is crucial to look at the applicability and extension of the radiological search system to other mission areas. Expanding the operational reach of the system to other mission areas would also increase the overall value for government and private entities. This increase in the asset's value could result in more emphasis on mission application, funding, maintenance, and development of future systems and system payloads. Providing a niche-solution to the radiological search mission will only attract niche customers. An infrequently used equipment set makes it challenging for the end user to reorient on system functionality and could lead to mechanical maintenance issues due to inactivity. Therefore, expanding the applicability of the system should be beneficial in terms of utility and cost effectiveness. Some consequences of expanding the mission coverage could include optional sizing of ground and air vehicles, the inclusion of a

1591 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

water-borne platform, and a more flexible vehicle architecture that can interface with numerous payloads.

In order to promote a flexible system that can apply to other missions, some modifications will need to be made. The system architecture is currently geared toward a radiological search mission with three specific vehicle options that all serve a certain purpose and accomplish certain tasks. There is some flexibility built into the system with separate modems for autopilot, video, and payloads. However, the promoted sizing for both the vehicle chassis and the power plant configurations are geared toward lifting a 6.8-kilogram payload for the multirotor and ground UVs as well as providing increased endurance for the fixed-wing UV by integrating a combustion engine. These narrowed solutions serve the purpose of meeting the intent established in the CONOPS. In order to provide a more comprehensive system, a new CONOPS and system architecture should be developed with a more holistic approach to incorporate current and emerging missions. As previously discussed, this would necessitate the customization of some hardware components such as the communication modem and processor suite in addition to on-board and GCS software. These additions would provide the capability for multiple vehicles to interchange payloads and the ability to reprogram system software to be compatible with a variety of components and data types.

Summary

The radiological search system has been characterized starting with the system CONOPS and resulting in the physical framework to meet the capabilities and assumptions determined by the CONOPS. Following the characterization of the system,

1592 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

a feasibility analysis considered the potential benefits and disadvantages that the system presents and must be evaluated when determining the overall utility of the system to the mission area. The analysis determined that the system could apply to current radiological search operations but may be limited to certain portions of the mission and constrained to specific organizations. Lastly, it was concluded that the system could be applied to other missions, but it may need to be modified to provide enhanced flexibility and a more refined product.

1593 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

V. Conclusions and Recommendations

Overview

Within the counter-WMD mission space, radiological and nuclear terrorism is an imminent and constant threat to United States national security. Developing and employing new technologies is crucial for safeguarding this nation, and a radiological search system is a potential solution to assist and strengthen the radiological search mission space. It would provide more execution options to responding personnel and the ability to remove the human element from hazardous situations.

Review of Findings

A CONOPS was developed by incorporating mission needs and constraints for radiological search operations. Utilizing the radiological search CONOPS, use cases and a functional decomposition were derived that account for the necessary tasks to complete radiological search missions. A physical architecture was created in order to allocate physical components to satisfy task completion. After completing the hierarchical decomposition, it is evident that the system necessitates a multidimensional construct with multiple vehicle platforms and distinct detector payloads that are governed by scenario or mission criteria. Each detector technology can be optimally applied to select portions of the radiological search mission, such as initial search operations or gamma spectrum collection. Similarly, certain vehicle platforms are ideal for or are limited to specific segments of the mission. In order to cover the gamut of radiological search mission tasks, the system needs multiple vehicle options and interchangeable detector

1594 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

payloads with an adaptable system framework. The conceptual system was found to be feasible in terms of constructability and operability based upon currently available technologies, but it may have limited application to the mission area. Hybrid-electric power plants would be a necessity for multirotor endurance and payload capacity, whereas fixed-wing vehicles could safely operate with battery or gasoline-powered options. In order to maximize the utility and effectiveness of the system to other DoD mission areas, the system needs to be expanded to provide more optionality for payload integration, vehicle selection, and software flexibility. This includes a universal system architecture and software suite that can adapt to emerging technologies and mission areas.

Study Limitations

The research was scoped to cover system application to radiological and nuclear material search and spectroscopy activities in the next two to five years. Assumptions guided the creation of the CONOPS, as user requirements for the system do not exist. The research did not incorporate consequence management surveying following accidents or terrorism activity involving nuclear or radiological materials. Content was limited to publicly available information and did not dwell at a higher-level of classification. Tactics, techniques, and procedures for the system were not covered, as the focus was characterizing the system and its operational feasibility and utility of the system to the radiological search mission. Lastly, research was limited by funding and time constraints.

1595 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Future Research

There are multiple avenues for future research involving unmanned systems to accomplish radiological search missions. Options align with a continuation of the Systems Engineering "V" concept by conducting a detailed system design, developing custom hardware or software for the vehicles and GCS, or completing a cost analysis of system procurement and lifecycle operating costs for the end user. Utilizing a decision-based engineering design framework will provide rigor to the engineering design process and ensures that value theory is applied to system development [51]. These additional areas would provide more tangible findings and insight to the system's utility when weighed against acquisition and recurring costs.

Another research opportunity is refining or building a new architecture to expand the radiological search system to multiple mission areas. The application of the system to other missions was briefly discussed in Chapter IV. This would include additional ground and air vehicles, waterborne vehicles for maritime operations, a custom communication and processing package, and custom system software for both the GCS and UVs. An extended application to current mission areas with the flexibility to cover emerging missions would greatly increase the utility and value of the system.

In Chapter IV's design considerations, employing handheld detectors on system vehicles was considered for increasing the flexibility of the overall system and avoiding a mission stoppage if conditions change. It would be beneficial to compare commonly used handheld detectors to COTS and GOTS detectors designed for vehicle applications. Detectors can be evaluated on performance in different radiation field configurations,

1596 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

vehicle emplacement options and limitations, integration with system hardware and software, and expected procurement and lifecycle costs.

Appendix B. System Use Cases

Description:
This Use Case encompasses deployment of the Rad Search System vehicle(s) and ingress to the search area.

Preconditions:
Successful completion of Perform Setup Use Case
GPS Lock

Primary Flow:
1. Ground Control Station Operator initiates Launch mode through Ground Control Station
2. Ground Control Station changes Vehicle mode to Launch
3. Vehicle enters Launch mode
4. Vehicle transmits telemetry to Ground Control Station(s)
5. Ground Control Station(s) receives and displays telemetry data
6. Ground Control Station(s) stores telemetry data
7. Ground Crew launches Vehicle
8. Vehicle establishes controlled movement or stable flight
9. Vehicle maneuvers toward search area
10. Ground Control Station Operator observes received data on Ground Control Station
11. Once Vehicle arrives at Search Insertion point, it enters Search mode
12. End Use Case

Alternate Flow:
At any time:
  a. If bad Vehicle health, Ground Control Station Operator enters RTL command on Ground Control Station
  b. Ground Control Station sends RTL command to Vehicle
  c. Vehicle enters RTL mode
At any time:
  a. Operator initiates <<include>> Plan Mission Use Case
  b. Vehicle ingresses to new Search Insertion point
At any time:
  a. If vehicle compromise is evident, execute <<extend>> Perform Self-Destruct Use Case

Postconditions: Vehicle arrives at Search Insertion point and enters Search mode

Involves:
GNSS
Ground Control Station Operator
Ground Crew

Figure 16. Deploy and ingress use case

1606 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Description:
This Use Case covers the RTL actions required to return the vehicle to home location or specified location with recovery.

Preconditions: Vehicle has entered RTL mode

Primary Flow:
1. Vehicle maneuvers toward home/recovery point
2. Vehicle arrives at home/recovery point
3. Vehicle executes auto-land maneuver
4. Ground Control Station Operator and Ground Crew recovers Vehicle
5. End Use Case

Alternate Flow: At any time:
a. If bad vehicle health, Ground Control Station Operator enters RTL command on Ground Control Station
b. Ground Control Station sends RTL command to Vehicle
c. Vehicle enters RTL mode
At any time:
a. Ground Control Station Operator initiates Plan Mission Use Case
b. Vehicle ingresses to new Search Insertion point
At any time:
a. If vehicle compromise is evident, execute <<extend>> Perform Self-Destruct Use Case

Postconditions: Vehicle is safely recovered by Ground Crew

Involves:
GNSS
Ground Control System Operator
Ground Crew

Figure 17. Egress and recover use case

1607 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Description:
This Use Case covers confirmation activities

Preconditions: Target has been located and a Vehicle has entered Confirmation mode

Primary Flow:
1. Vehicle transmits telemetry data, rad data, and video to Ground Control Station(s) and Off-Board C2
2. Ground Control Station(s) receives and displays telemetry data, rad data, and video
3. Ground Control Station(s) stores telemetry data, rad data, and video
4. Vehicle navigates to and hovers or remains near target
5. Ground Control Station sends collect rad spectrum data command
6. Vehicle receives and initiates rad spectrum collection
7. Vehicle transmits rad spectrum data
8. Ground Control Station(s) receives, stores, and displays rad spectrum data
9. Ground Control Station Operator terminates rad spectrum collection
10. Ground Control Station processes rad spectrum data and displays radionuclide identification
11. Ground Control Station Operator initiates RTL
12. Ground Control Station sends RTL command to Vehicle
13. Vehicle enters RTL mode
14. End Use Case

Alternate Flow:
At any time:
a. If bad vehicle health, Ground Control Station Operator enters RTL command on Ground Control Station
b. Ground Control Station sends RTL command to Vehicle
c. Vehicle enters RTL mode
At any time:
a. If vehicle no longer required due to deployed sensor package, Ground Control Station Operator enters RTL command
b. Ground Control Station sends RTL command to Vehicle
c. Vehicle enters RTL mode
At any time:
a. Ground Control Station Operator initiates <<include>> Plan Mission Use Case
b. Vehicle ingresses to new Search Insertion point or Confirmation coordinates
At any time:
a. If vehicle compromise is evident, execute <<extend>> Perform Self-Destruct Use Case
b. Vehicle self-destructs

Postconditions: Vehicle hovers or remains near target for > 5 minutes and rad spectrum is stored and displayed on Ground Control Station(s) with suspected radionuclide identification; Vehicle enters RTL mode

Involves:
GNSS
Off-Board C2 Operator
Target

Figure 18. Perform confirmation use case

1608 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Description:
This Use Case covers execution of search patterns

Preconditions: Vehicle arrives at insertion point and has transitioned to Search mode; Mission Plan is loaded by GCS

Primary Flow:
1. Vehicle transmits telemetry data, rad data, and video to Ground Control Station(s) and Off-Board C2
2. Ground Control Station(s) receives and displays telemetry data, rad data, and video
3. Ground Control Station(s) continuously combines telemetry and rad data and displays as a radiation strength map
3. Ground Control Station(s) stores telemetry data, rad data, and video
4. Vehicle follows search pattern according to Mission Plan
5. Ground Control Station Operator and Off-Board C2 monitor rad data, navigation data, and video
6. Vehicle completes search pattern according to Mission Plan
7. Ground Control Station determines target(s) coordinates from received rad data and telemetry data
8. Ground Control Station Operator commands change to Confirmation mode
9. Ground Control Station sends Confirmation mode change
10. Vehicle enters Confirmation mode
11. End Use Case

Alternate Flow:
At any time:
  a. If bad vehicle health, Ground Control Station Operator enters RTL command
  b. Ground Control Station sends RTL command to Vehicle
  c. Vehicle enters RTL mode
At any time:
  a. If vehicle no longer required due to deployed sensor package, Ground Control Station Operator enters RTL command
  b. Ground Control Station sends RTL command to Vehicle
  c. Vehicle enters RTL mode
At any time:
  a. Ground Control Station Operator initiates <<include>> Plan Mission Use Case
  b. Vehicle ingresses to new Search Insertion point (may be used to further loiter or investigate target location)
At any time:
  a. If vehicle compromise is evident, execute <<extend>> Perform Self-Destruct Use Case
  b. Vehicle self-destructs

Postconditions: Target is identified through radiation sensor data and telemetry data and target coordinates are calculated and displayed on Ground Control Station(s); Vehicle transitions to Confirmation mode

Involves:
GNSS
Off-Board C2 Operator
Target

Figure 19. Perform search use case

1609 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Description:
This Use Case covers the activities required to perform commanded self-destruct.

Preconditions: Vehicle is navigating in a location away from the Ground Control Station Operator

Primary Flow:
1. Operator initiates Ditch mode on Ground Control Station
2. Ground Control Station sends Self-Destruct mode change to Vehicle
3. Vehicle initiates Self-Destruct mode
4. Vehicle processor sends command to A/P to crash
5. Vehicle processor sends command to embedded self-destruct actuator
6. Embedded self-destruct actuator initiates and destroys processor
7. Vehicle crashes
8. End Use Case

Postconditions: Vehicle is successfully crashed and system is inoperable by other personnel

Figure 20. Perform self-destruct use case

1610 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Description:
This Use Case covers the setup and mission planning for use of the Rad Search System

Preconditions:
Tasking received
Search area defined
Desired radionuclide(s) specified

Primary Flow:
1. Ground Crew and Ground Control Station Operator unpacks equipment
2. Ground Crew and Ground Control Station Operator inventories equipment
  2a. If necessary equipment missing - end Use Case
3. Ground Crew and Ground Control Station Operator assembles equipment
4. Ground Crew and Ground Control Station Operator initiate connection between Ground Control Station and Vehicle(s)
5. Ground Control Station sends connect signal to Vehicle(s)
6. Vehicle(s) makes connection to Ground Control Station
  6a. If connection fails, go to step 4. If fail 3x, end Use Case
7. Vehicle(s) begins transmission of rad data, rad spectrum data, telemetry data, and video
8. Ground Control Station displays rad data, rad spectrum data, telemetry data, and video
9. Ground Control Station stores rad data, rad spectrum data, telemetry data, and video
10. Ground Control Station Operator initiates function checks through Ground Control Station
11. Ground Control Station initiates function checks on Vehicle(s)
12. Vehicle(s) performs function checks and sends results to Ground Control Station
13. Ground Control Station displays results of function checks
14. Ground Control Station Operator confirms successful function checks.
  14a. If function check unsuccessful, go to step 10. If fail 3x, end Use Case.
15. <<Include>> Perform Mission Plan
  15a. If Mission Plan unsuccessful, repeat step 15. If fail 3x, end Use Case
16. End Use Case

Postconditions: System properly configured; mission planning complete; system ready for deployment

Involves:
Ground Control Station Operator
Ground Crew
GNSS

Figure 21. Perform setup use case

1611 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Description:
This Use Case covers actions associated with planning or re-planning a mission. It can be completed either pre-, or post-launch.

Preconditions: Vehicle has passed function checks and has established comm with Ground Control Station(s)

Primary Flow:
1. Ground Control Station Operator enters Mission Plan information into Ground Control Station
2. Ground Control Station converts Mission Plan to machine language form
3. Ground Control Station Operator initiates Write Mission Plan function on Ground Control Station
3. Ground Control Station sends machine language Mission Plan to Vehicle(s)
4. Vehicle(s) puts Mission Plan into active memory
5. Vehicle(s) sends indication of successful Mission Plan
6. Ground Station displays indication of successful Mission Plan load
7. End Use Case

Postconditions: Successful receipt of Mission Plan by Vehicle(s)

Figure 22. Plan mission use case

Captain Sam B. Harriger graduated from the United States Air Force Academy in 2011 where he received his commission and a Bachelor of Science in Environmental Engineering. After commissioning, Captain Harriger served in several Civil Engineering positions at Beale Air Force Base, California, including wastewater environmental compliance, aircraft beddown planning, and construction project management. He also deployed to southwest Asia, where he led five teams across seven countries providing runway rubber removal, airfield paint striping, and large area maintenance shelter construction. Captain Harriger's most recent assignments include serving as the 377th Explosive Ordnance Disposal (EOD) Flight Commander and as the EOD Section Chief at the Defense Nuclear Weapons School at Kirtland Air Force Base, New Mexico. In 2018, he was selected to attend the Air Force Institute of Technology at Wright Patterson Air Force Base, Ohio as part of the Graduate Engineering Management program. Following graduation and earning a Master of Science in Engineering Management, Captain Harriger is deploying to Africa to serve as a United Nations Staff Officer.

14. ABSTRACT

Nuclear and radiological terrorism is a persistent threat to United States national security. The research and development of new technological capabilities is vital to bolstering emergency response and prevention capabilities in support of national security initiatives. This research characterized the applicable trade-space for a system of unmanned vehicles deployed for search, detection, and identification of radiological source material. Exploration included the development of a CONOPS, a functional decomposition and physical allocation, design considerations, and an analysis of feasibility and utility. The concept system comprises of a ground control station, ground vehicle, hybrid-electric multirotor, and fixed-wing vehicle with an open architecture permitting the exchange of payload components. Payload options include a Geiger-Müller detector or scintillator for large area search and a scintillator or high purity germanium semiconductor for radioisotope identification. Endurance estimates revealed that a hybrid-electric multirotor is capable of carrying a 6.8-kilogram payload for 58 minutes. Similar estimates indicated that a battery-powered fixed-wing vehicle can provide a minimum of 41 minutes of endurance with a payload mass fraction of 15% (1.36-kilogram payload), whereas a gasoline-powered vehicle with the same payload mass fraction (1.95-kilogram payload) can operate for 12 hours. Electric multirotors are limited to a maximum endurance of 20 minutes, which is insufficient for radiological search missions. The system concept proves effective to the radiological search mission and can be expanded to other mission areas through its open architecture.

14. ABSTRACT

In an ever-increasing complex world, the United States Army aims to modernize and innovate to meet emerging threats. This modernization is no less apparent than the changes observed in Army Information Collection resources and processes over the last thirty years. During this time, the Army has organized information collection platforms around the Brigade Combat Team without resourcing a collection manager at the Brigade Combat Team. This research seeks to determine the value of authorizing a collection manager position on the Brigade Combat Team Modified Table of Organization and Equipment. Through extensive qualitative analysis of doctrine, force management references, and professional writing from the past thirty years, this research found that the position of a collection manager provided expertise in coordinating information collection processes, producing information collection tools, and integrating information collection systems to support the commander's decision making.

ACKNOWLEDGMENTS

This thesis represents the culmination of almost two years of the study of collection management in the United States Army and Joint Force. This work would not have been possible without the hard work and dedication of a team of true professionals. First, I thank Lieutenant Colonel (retired) Jimmy Gaw for his mentorship and encouragement to embark on this collection management quest in the Army Intelligence Development Program-Intelligence, Surveillance, and Reconnaissance.

Second, to my research committee of past and present members; Mrs. Candy Smith, Dr. Frank James Jr., Mr. Gregory Butts, and Mr. William Stebbins, I offer my sincere gratitude for your guidance and patience throughout this research process. Your motivation and feedback were invaluable to make this thesis a reality.

Third, the knowledge and experience of Mr. Russell Rafferty, Mr. John Dubuisson, and the rest of the Combined Arms Research Library Staff contributed to the level of historical data necessary to understand the whole story of collection management from Operation Desert Storm to present day. Your assistance through countless questions and many hours of microfilm scanning cannot be overstated, nor your ability to direct me to the best data to build the collection management story.

Lastly and most importantly, to my loving family, my wife and son, I thank you for your patience and encouragement throughout this research process. Your consistent support through many hours of reading and writing, questioning and doubting reminds me of the true love we share. I owe this work and so much more to both of you.

CHAPTER 1

INTRODUCTION

The United States Army is currently undertaking significant efforts to modernize for future threats while continuing efforts to combat existing threats and maintain readiness. These efforts are evident as the Army shifts from counter-insurgency based operations to Large Scale Combat Operations (LSCO) including shifting to near-peer threat emulation at the combat training centers as well as updates to Army doctrine, starting with operations. As such, the Chief of Staff of the Army, General Milley, made readiness and the future Army as two priorities Army-wide.[1] As part of realigning strategy, Lieutenant General Robert Ashley, the Army G-2, developed the *Army Intelligence 2017-2025* to support the modernization efforts across the Army. The intelligence strategy seeks to "integrate the national to tactical intelligence enterprise with multi-domain operations to provide a high degree of situation understanding"[2] with the vision of "intelligence at the speed of mission command."[3]

The 2025 intelligence vision, nested with the Army Strategic Plan, lists synchronization of information collection efforts as the first competency of focus.[4] The vision further highlights the complexity of the future operating environment where near-peer or peer adversaries have capabilities to combat the US militaries relative dominance in information collection across all operating domains.[5] The 2025 intelligence vision identifies two major objectives with direct correlation to information collection management: fostering professionalization and manage talent, and fielding superior sensors.[6] Fostering professionalization and manage talent corresponds to the skills and abilities required for collection managers (CMs) to effectively employ collection

1632 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

platforms to drive operations and support the commander's visualization. The fielding of superior sensors speaks to the growing complexity of the operational environment into a truly multi-domain operational construct where current collection platforms are ineffective against peer adversaries' anti-access and area denial capabilities. The need for knowledgeable integrators through collection management will grow as information collection capabilities continue to advance through the Army's shift from counter-insurgency focus to multi-domain operations against a peer threat. The 2025 strategy provides the framework for how Army intelligence will prepare for the future fight by prioritizing efforts that ultimately drive budgetary decision, such as the fielding of new information collection platforms.

Intelligence collection represents a significant funding investment by the United States Government to answer the critical information requirements of civilian leaders and military commanders. A 2011 Government Accountability Office report highlighted the considerable growth in intelligence collection capabilities and expenditures to the sum of $80 billion dollars for fiscal year 2010 across the intelligence community.[7] Of this figure, for fiscal year 2010, "the defense intelligence budget, known as the Military Intelligence Program," comprised $27 billion in an environment where distinct collection activities and platforms between national and tactical levels were disappearing.[8] The blurring "between military intelligence activities and national strategic intelligence activities" of the platforms and intelligence consumers demonstrates that tactical consumers benefit from greater access to information collection capabilities than previously available just as national consumers are utilizing intelligence collected from tactical level platforms.[9] Further, these funding investments have historically not included dual use programs such

1633 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

as the Air Forces Reaper, as a collection and strike platform, as well as the military personnel expenses associated with intelligence activities which in some cases significantly underestimates the actual cost.[10] The availability of information collection platforms between echelons is largely a product of protracted counter-insurgency operations from Operations Iraqi Freedom and Enduring Freedom, enabled by advances in communications capabilities to widely disseminate information. The downward push of capabilities to the tactical-level was reinforced by the dynamic shift in Army operational construct from a Corps and Division warfighter to a modular Brigade Combat Team necessary to conduct effective counter-insurgency operations, necessitating significant investment in collection capabilities. As time progressed, terms like "Intelligence, Surveillance, and Reconnaissance (ISR) Soak", came to embody the availability of a multitude of information collection platforms at the Brigade Combat Team-level. Whereas Operations Iraqi Freedom and Enduring Freedom represent the epitome of information collection capability proliferation to meet operational needs, the first true test of highly technical information collection capabilities in support of large-scale combat operations came in Operation Desert Storm.

Operation Desert Storm provides context to the development and fielding of collection platforms over the last thirty years as the most recent example of large-scale combat operations. Likewise, this time period is illustrative of the highly technological approach to information collection and justification of significant budgetary investments. Operation Desert Storm saw the introduction of two significant collection platforms, the Unmanned Aerial System (UAS) and the Joint Surveillance and Target Attack Radar System (JSTARS).[11] Both systems deployed to Operation Desert Storm as prototypes to

1634 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

support the largely imagery dominated campaign.[12] The Pioneer UAS served as a Corps level platform while the JSTARS, an Air Force platform, supported both air component and Field Army targeting and intelligence development.[13] Further, both systems were praised heavily for their contributions and leaders from 3rd Army encouraged expansion and fielding of these platforms.[14] One conclusion the 3rd Army G-2 made after Operation Desert Storm is that the advancements in collection platforms and the ability of the American Soldier to leverage that technology were critical elements of success.[15] Where Operation Desert Storm demonstrated the ability to leverage new and existing national and tactical intelligence collection platforms in large scale combat operations, it highlighted the need for training in integrating and synchronizing these systems across echelons.

Leaders from Operation Desert Storm reinforced the need for "highly-trained intelligence personnel who can orchestrate multi-echelon collection management and dissemination operations" to provide "synchronized collection, processing, and dissemination of near-real-time, tailored intelligence."[16] This identified need, borne of experience, led to updates in the Army's collection management and tactical exploitation of national capabilities course designed to leverage the new, emerging information collection platforms identified earlier. The three-week collection management and tactical exploitation of national capabilities course represented the United States Army Intelligence Center of Excellence (UASICoE) efforts to fill the capability gap.[17] This Army school solution aimed at training multi-echelon capable collection managers. While the Intelligence Center developed this broader scoped training solution, the United

1635 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

States Army Intelligence and Security Command (INSCOM) sought a smaller education program of depth.

In 1992 INSCOM started the National Systems Development Program as an advanced training program for junior military intelligence officers in integrating national collection systems to support warfighters at the division and below level.[18] INSCOM later changed the name of this program to the Army Intelligence Development Program-ISR (AIDP-ISR).[19] No direct correlation exists in the unclassified literature between lessons learned in Operation Desert Storm with the creation of the National Systems Development Program, later AIDP-ISR. The current twelve-month training program assigns graduates as a collection manager at a U.S. Army Division or Corps for a twelve to twenty-four-month utilization tour to apply skills gained in collection management.[20] The program includes a variety of Army, Joint, and national training that covers collection capabilities, collection requirements management systems, collection management fundamentals, and integrating courses.

Collection capabilities focus primarily on distinct courses in the intelligence disciplines of Signals intelligence, Geo-Spatial Intelligence, and Human Intelligence. National-level courses at the Defense Intelligence Agency, the Department of Defense Collection Management proponent, provide exposure to collection management fundamentals and the collection requirements management systems to build proficiency in actually submitting requests for collection to national collection systems. Tactical-level collection management training occurs through USAICoEs Information Collection Planners Course. Integrating courses include examples such as the US Army Space Cadre with thorough orbital dynamics instruction and the Joint Firepower Course providing

1636 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

exposure to US Air Force resources and processes. The AIDP-ISR student's instruction culminates with participation in a Division Warfighter Exercise as a member of the Division Collection Management and Dissemination (CM&D) section. This exercise introduces the student to the array of information collection platforms at the Division and BCT levels.

The operational environment grows more complex everyday. The US Army, through INSCOM and USAICoE, continues to innovate through the development and acquisition of collection capabilities. The growth of unmanned and multi-intelligence discipline collection platforms bring more sensors and capabilities to maneuver commanders than previously available.[21] INSCOM's fielding of four unique manned and unmanned aerial collection platforms, the Enhanced Medium Altitude Reconnaissance and Surveillance System, Airborne Reconnaissance Low-Enhanced, MQ-1B Warrior Alpha, and MQ-1C Gray Eagle represent a sampling of the updated and emerging capabilities at echelons above brigade that collection managers can consider in developing collection plans.[22] At the time of the 2011 Government Accountability Office report on the Department of Defense ISR efficiencies, the department was attempting to develop long-term plans for "more than 500 ISR capabilities developed to meet urgent operational requirements in Iraq and Afghanistan" as a further example of the overwhelming collection capability environment.[23] Intelligence leaders foretold of this complex environment in 1992 while contemplating force structure changes.

> The evolving force structure calls for a smaller Army, mainly a CONUS-based force. The Army of the future must be able to deter potential regional threats and conflicts globally, instead of focusing primarily on European-based threats. This mission includes deterrence not only of mid- and high- intensity conflict, but also low-intensity conflict. The evolving threats include –

1637 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- Nuclear and conventional forces of the Commonwealth of Independent States.
- Multiple regional threats from state and non-state powers in the Middle East, Asia, Africa, and Latin America.
- International drug trafficking.
- International Terrorism.[24]

The development of the BCT-centric capability came from force modernization plans based on lessons learned from small-scale contingency operations, such as Kosovo, resulting in the desire for a formation between the traditional heavy armor and light infantry.[25] In his estimations, Chief of Staff of the Army, General Eric Shinseki, concluded that future fights would require a force structure capable of rapid deployment but enabled with enough mobility and lethality to handle the transition from forced entry to sustained combat.[26] Two fundamental components of the BCT development are the Reconnaissance, Surveillance, and Target Acquisition Cavalry Squadron and the Military Intelligence Company (MICO). These organizations were designed to provide the BCT with significant organic information collection capabilities not previously available at the Brigade-level. The Cavalry Squadron included a surveillance troop of a UAS platform, signals intelligence collectors, and chemical reconnaissance to augment the three ground reconnaissance troops.[27] Separate from the cavalry squadron, a MICO consisting of human intelligence, ISR analysis, and ISR integration platoons served as the requirements management and analytical element for the BCT's new array of ground reconnaissance, UAS, human intelligence and signals intelligence collection platforms.[28] Through further modernization, the surveillance troop disappeared with the UAS and signals intelligence platforms moved to the MICO that now resides in the Brigade Engineer Battalion. The ISR analysis and integration platoons are consolidated into an

1638 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

information collection platoon adding analysis and synchronization requirements to fewer Soldiers. This increase in responsibilities to fewer Soldiers, coupled with the number of collection platforms within the BCT, results in a lack of integration in the information collection plan. This result is borne out in numerous combat training center rotation feedback and identified trends.

Problem

Brigade Combat Teams have access to vastly more collection platform capabilities than their counterpart formations during Operation Desert Storm as the model of the most recent LSCO. Currently, no authorized collection manager position exists in the BCT to support the integrated operations and intelligence working group responsible for developing a comprehensive information collection plan. To fulfill the requirements of collection management, BCTs designate a collection manager as an additional duty.

Thesis

The Brigade Combat Team needs an authorized, primary duty collection manager on the Modified Table of Organizational Equipment (MTOE) to integrate collection management processes with information collection systems through effective information collection tools to answer the commander's requirements.

Research Purpose

The purpose of this research is to determine the benefit of authorizing a collection manager position in the BCT MTOE with advanced training in information collection management to support the BCTs information collection operations.

1639 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Research Question

What is the value of an authorized BCT collection manager in the MTOE as BCTs prepare for offensive and defensive operations with a near-peer threat in LSCO?

Supporting Research Questions

How does the BCT doctrinally execute information collection?

How have organic collection platforms available to the BCT changed over the last three decades?

What institutional and operational knowledge is necessary for a BCT CM?

Background and Bias

The researcher served in a variety of tactical-level positions related to information collection to include reconnaissance platoon leader, surveillance troop executive officer, battalion S-2, and AIDP-ISR student. Author's AIDP-ISR training and education includes the Army's Information Collection Planners Course, Defense Intelligence Agency's Intelligence Collectors Course and Intelligence Collection Management Course. Additionally, the researcher attended in-depth education covering capabilities and requirements management systems in the Geospatial, Signals, and Human Intelligence disciplines. Beyond collection management, the author attended integrating education in joint fires and digital intelligence systems architecture. The researcher acknowledges the inherent possibility of bias towards the role of the collection manager as a graduate of the AIDP-ISR program. In light of this bias, the author intends to show a variety of viewpoints objectively regarding improvements to information collection at the BCT. Lastly, the researcher recognizes that, as a Military Intelligence Officer, the research may

1640 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

appear framed from a military intelligence perspective. However, the researcher has never served as a BCT collection manager or supervised a BCT collection manager. To address the inherent Military Intelligence lean, this research intends to include the reconnaissance communities' perspective wherever possible.

Assumptions

The main assumption of this research is that information collection platforms available to the BCT will continue to grow. This assumption is largely based on lessons learned from Operations Desert Shield, Desert Storm, Iraqi Freedom, and Enduring Freedom. From Operation Desert Storm, "the field Army focused nearly all intelligence collection and production on Corps and Division needs" demonstrating a push of collection platforms to subordinate units.[29] The next assumption presumes the audience has a general understanding of the composition of a BCT to the company level, specifically enabler companies such as the Military Intelligence Company. The last assumption is the audience has a general understanding of the information collection capabilities organic to the BCT. This assumption is necessary to keep this research at the unclassified level as discussion of specific collection platform capabilities can quickly elevate the information to higher classification levels unnecessary for this discussion.

Definitions

The primary definition, for the purposes of this research, of Information Collection, is defined in the Army's manual as "an activity that synchronizes and integrates the planning and employment of sensors and assets as well as the processing, exploitation, and dissemination systems in direct support of current and future

1641 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

operations."[30] Sensor and asset must be defined for further clarity in the research as no formal definition exists in either Army or Joint doctrine. Oxford Dictionaries defines a sensor as a "device which detects or measures a physical property and records, indicates, or otherwise responds to it."[31] Given this definition, this research considers a sensor as a technical collection platform that transmits data for processing and analysis. Sensor collection systems associate most closely with the intelligence disciplines of Geospatial (GEOINT), Signals (SIGINT), Measures and Signatures (MASINT).

Assets are more loosely defined with Oxford Dictionaries offering as "a useful or valuable thing or person."[32] Given the broad scope of the term asset, this research considers a collection asset as a human dependent collector. Asset collectors are associated with Human Intelligence, Counter-Intelligence, and Cavalry Scouts performing reconnaissance and security operations. To further clarify, Cavalry scouts are capable of utilizing sensors, such as the long-range scout surveillance system, but for this research, the scout is the asset as the data is processed and reported by the scout as combat information.

A collection platform is inclusive of a sensor or an asset or a combination of multiple sensors or assets. A collection platform also includes the means of transportation and data communication. An example of a collection platform would be a Cavalry Scout section consisting of two combat vehicles equipped with long range scout surveillance systems as the sensors and eight Cavalry Scouts as the assets.

Two terms must be clarified in the leveraging of a collection platform against an information requirement. The terms of assigning versus tasking may, at face value, appear similar but, in reality, carry different weight in collection management.

1642 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Doctrinally, unless dictated otherwise, the Commander and the S-3 are the two tasking authorities in the BCT. Staff supports the tasking authority through assignment recommendations to free the commander and S-3 to focus on other requirements of the operations process and mission command. This distinction is critical to the base understanding of the role of the collection manager. As a manager, the collection manager is a staff member making assignment recommendations to the Commander and S-3.[33] This distinction reflects in Army Information Collection doctrine as an operations series Field Manual (FM).

The Army definition of information collection is virtually identical to the joint definition of Intelligence, Surveillance and Reconnaissance (ISR) that is "an integrated operations and intelligence activity that synchronizes and integrates the planning and operations of sensors, assets, and processing, exploitation, and dissemination systems in direct support of current and future operations."[34] That stated, ISR is also a composition of three sub-elements as the acronym suggests with distinct characteristics differentiating them from one another. To fully understand the concept of ISR, one must first understand that intelligence exists in a product sense and operational sense. The product sense starts with the difference between data, information, and intelligence. Data exists in raw form and can be collected by a sensor or asset becoming information. Intelligence is information that has been processed and exploited by a trained analyst to derive meaning from the information collected. Intelligence in an operational sense are "tasks undertaken by military intelligence units and Soldiers to obtain information to satisfy validated requirements," and associated with one or more intelligence discipline; therefore, a form of collection operation.[35] Reconnaissance collection operations are focused on "obtaining

1643 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

information about the threat or the operational environment," whereas surveillance operations are a "systematic observation of places, person, or things."[36] Think of reconnaissance as cavalry scouts observing a named area of interest to confirm or deny an aspect of the threat or operational environment and then moving on to the next named area of interest after answering the first. Surveillance in this example would be establishing a longer duration presence by the same cavalry scouts to observe a threats activity and provide continuous reporting. Coupled together, ISR provides a wholistic approach to collecting information with intelligence and non-intelligence related sensors and assets.

Joint Collection Management Functions Defined

The two functions of collection management, as defined by Joint Pub 2-01, is necessary to understand roles and responsibilities associated with collection management as a process. The first is Collection Requirements Management (CRM) where a collection manager is responsible for validating the determined information requirements as necessary for collection.[37] The second is Collection Operations Management (COM) where a collection manager is responsible for assigning a collection platform to collect the information determined through the collection requirements management.[38] An associated, but not critical function, is Collection Mission Management (CMM) which is the tactical and technical control of a sensor or asset during collection operations. To summarize collection management functions, an analyst recommends a threat's indirect fires equipment as an information requirement that supports the commander's Priority Intelligence Requirements to the senior intelligence analyst in the Brigade Intelligence Support Element. The senior analyst includes the recommended information requirement

1644 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

along with additional information requirements such as location of threat forward observers to the collection manager for assigning a collection platform to collect. In this previous example, the senior analyst performs CRM functions while the collection manager performs COM functions. CMM rests with the organization that has direct command and control of the collection platform, in the example, CMM would be the parent unit of the forward observer. The examples provided to explain the joint collection management functions applied to a brigade are for illustrative purposes to understand the functions since current U.S. Army doctrine does not differentiate the roles in a U.S. Army capacity.

Scope

The intent of this research is to be applicable to all BCT organizations as every construct of the BCT fundamentally maintains an intelligence section, MICO, and cavalry squadron. The primary audience for this research is senior Military Intelligence leaders with influence on intelligence organization force structure and training. Brigade Combat Team Commanders and Division Senior Intelligence Officers are the secondary audience for this research as a means for manning and training of military intelligence within their respective commands. Collection platform diversity over the last three decades highlights the development of technical collection platforms available to the BCT. This timeframe includes LSCO in Operation Desert Storm, and both LSCO and Counter-Insurgency in Operations Iraqi Freedom and Enduring Freedom. The intent of this timeframe is to show that collection platform diversity has grown regardless of the nature of military conflict since 1990.

1645 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Limitations

The primary limitation of the research is the Brigade Combat Team as an echelon and combat organization. The purpose of the limitation is to focus the research on primary maneuver forces projected to be engaged in offensive and defensive operations against a near pear threat. The research is further limited to the Brigade Combat Team's intelligence warfighting function, the cavalry squadron, and the brigade operations staff section. Where necessary, the research includes discussion of division level organizations for historical context only.

Delimitations

This research does not discuss operational capabilities of specific collection platforms or intelligence disciplines due to the sensitive or classified nature of specific platforms. Further, this research does not include aggregated details of force management documents to prevent disclosure of unclassified but sensitive information. Force management information is limited to specific references to duty positions and additional skill identifiers indicating authorizations for advanced training.

Significance of the Study

This research examines the BCT information collection organizational structure, operational planning, and employment of BCT assigned collection platforms, including scouts and technical collection platforms. The U.S. Army maintains three types of brigade combat teams, each equipped with the bulk of tactical information collection assets. This research may contribute to justification of personnel decisions for the BCT as well as training recommendations to better support information collection.

1646 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Summary

Information collection in the United States Army represents a significant investment in strategy and force management in both material and personnel. The United States Government invests significant resources to staff and equip intelligence organizations to provide information for decision makers from tactical to strategic levels.

CHAPTER 2

LITERATURE REVIEW

The literature for this research consists of three main categories; doctrine, professional discourse, and personnel management references. The doctrine research covers a wide span of proponents as the nature of information collection is not limited to one single warfighting function responsibility. Therefore, the doctrine literature incorporates contributions from both the intelligence and movement and maneuver warfighting functions. The doctrine literature also includes discussion on joint doctrine since current information collection operations are heavily reliant on joint collection platforms. In short, the majority of literature found for this research was centered on information collection at the BCT which aligns with the overall purpose being to determine the benefit of an authorized collection manager position in the BCT MTOE.

The military professional literature encompasses a variety of sources from the intelligence warfighting function, the movement and maneuver warfighting function, joint observations, and historical observations from Operation Desert Storm. The military intelligence literature comes primarily from *Military Intelligence Professional Bulletin* articles discussing intelligence contribution to information collection and also leader commentary on the AIDP-ISR contributions to corps and division capabilities. Reports on intelligence operations during Operation Desert Storm provides a historical component of the military intelligence literature.

Military professional literature from the movement and maneuver warfighting function includes discussions on expectations of the intelligence warfighting function support to reconnaissance and Cavalry leader involvement in information collection

1651 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

management. In all, the prevailing discussions center around experientially based recommendations to improve Army information collection with specific emphasis at the BCT-level. Further, the literature review is organized based on the supporting research questions of how the BCT doctrinally conducts information collection, collection platform development at the BCT over the last three decades, and necessary knowledge of a BCT collection manager followed by general discussions of the collection manager at the BCT. The literature review concludes with major themes found throughout the literature that informed the overall thesis and drives the research methodology.

Improving Information Collection

The majority of the professional discourse literature focuses on improving the information collection capabilities within respective units based on direct observations and experiences, mostly through combat training center rotations. Most literature made recommendations on improving coordination during collection management activities, information collection tools, or knowledge of information collection systems. None of the literature researched clearly identified a need for standardizing the collection manager position at the BCT on the MTOE. The literature represents a diverse group of contributors with many having served as a BCT collection manager in multiple capacities, although their recommendations focused on training and coordination amongst the staff that is reflected in doctrine. Some recommendations represented fundamental organizational, equipping, and operational changes at the BCT and were the minority.

The dual-hatted capacity is represented in the case with First Lieutenant Anthony Sterioti, an Information Collection Platoon Leader and BCT collection manager. Sterioti offered a concise description of the information collection process in the BCT with

1652 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

specific emphasis on the work of the collection working group and relationship with the S-3 staff.[1]

Recent doctrine updates across the Army is represented in Ms. Terri Lobdell's article on "Resetting Intelligence Doctrine". Lobdell, a key Army Civilian in the Doctrine Integration Branch at USAICoE, presents the contextual changes for FM 2-0 brought about from the release of FM 3-0, *Operations*.[2] Lobdell includes refinement of intelligence tasks, specifically Intelligence Preparation of the Battlefield and collection management, as new focus in the updated FM 2-0 with concerted efforts to maintain fundamentals such as intelligence operations within information collection and integration of national to tactical intelligence.[3]

In terms of theses, two significant studies appeared related to improving information collection or ISR, depending on the time of publishing. Major Ryan Skaggs, an Air Force officer, authored a thesis of applying mission command principles to improve agility in joint ISR.[4] As part of this thesis, Skaggs explored a notion of a dichotomy between ISR management and leadership positing the question if ISR should be managed or led.[5] Skaggs approach and research draws from doctrinal references of ISR being a managed process ultimately leading to a conclusion that ISR can be both managed and led effectively.[6] Major Aaron Sammons in 2008 focused on doctrinal and organizational changes to better serve the BCT commander's requirements. Sammons' research identified a capability gap at the BCT-level in a qualified manager endowed with the authority to direct ISR. In Sammons conclusion, the BCT needs "truly qualified officers [who] are, preferably, both educated and experienced in the direction of ISR…imbued with both the responsibility and the authority to direct ISR."[7] Sammons'

1653 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

argument directly targets the dichotomy of responsibility for information collection planning with the S-3 overall responsible for publishing orders where the S-2 contributes the lion's share of the plan.

The most consequential intelligence-focused professional discourse came from Combat Training Center Trainer's Major Nathan Adams, Captain Raymond Kuderka, Captain Andrew Eickbush, and Major Michael Childs, whose roles provided the greatest breadth of first-hand observation. Adams observed a total of eleven Combat Training Center rotations as an intelligence trainer at the Joint Readiness Training Center in Fort Polk, Louisiana.[8] In his experience, Adams provides specific details on numerous challenges within the BCT intelligence warfighting function with the most notable being synchronizing collection efforts across the staff beyond the creation of doctrinal tools.[9] Adams also identifies challenges in S-2 leadership, intelligence architecture, and asset management as areas for improvement.[10] Childs' experience stems from direct observation of fifteen rotations at the National Training Center in Fort Irwin, California from January 2011 through June 2012.[11]

Kuderka and Eickbush provided observational experience of Brigade Combat Teams and multi-national partners at the Joint Multinational Readiness Center in Hohenfels, Germany as an intelligence trainer and fires trainer respectively. Without providing context of a number of observed rotations, Kuderka and Eickbush note that, "regardless of unit type or nation of origin, units fail to plan and execute an information collection plan that supports the commander's decision-making process."[12] Kuderka and Eickbush state that ill-defined "operational framework, convoluted information collection overlays, lack of understanding organic information collection capability, prioritization of

1654 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

assets, and inadequate staff coordination" are the fundamental challenges with effective information collection planning and execution.[13]

Childs' observations, as an intelligence trainer, led to a major theme of BCTs failing to "practice effective information collection rehearsals to synchronize the brigade's reconnaissance and surveillance plan inside the intelligence warfighting function."[14] Ultimately the conclusions from Combat Training Center trainers demonstrate clear challenges within Army Information Collection planning and execution. The fact that information collection challenges in planning and execution come from across all the combat training centers cannot be overstated.

The recommendations with the most structural change came from experiences based on the permanent opposing force from the National Training Center at Fort Irwin, California. This article from a former BCT MICO Commander recommends restructuring the BCT MICO with their existing collection platforms and transferring the company to the Cavalry Squadron.[15] Wellsandt argues for transforming the MICO into a "Hunter Company", by stripping out the UAS platoon and augmenting the company with cavalry or infantry Soldiers.[16] Wellsandt's recommendation requires the entire BCT information collection structure to change as well as add material solutions in the form of ground surveillance radar, similar to what is used at the National Training Center.[17]

Outside of the Intelligence warfighting function, the cavalry community developed the concept of the Chief of Reconnaissance as a staff advisor role responsible for the integration of reconnaissance into the BCTs plans and operations. Two authors contributed to the Chief of Reconnaissance discussion by recommending a certain position in the BCT as ideal to serve as the Chief of Reconnaissance. The first

1655 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

perspective came from Captain Michael Hefti arguing that the Cavalry Squadron Headquarters and Headquarters Troop Commander is ideal. The second opinion, by Captain John Palmer, suggested the Cavalry Squadron Commander is the best suited to fulfill the role of Chief of Reconnaissance. Both authors acknowledge the lack of any information or defining qualities of the Chief or Reconnaissance in doctrine.

Hefti argues that the Cavalry Squadron Headquarters and Headquarters Troop Commander makes the ideal candidate to serve as the BCT Chief of Reconnaissance because the doctrinal role and position of the Headquarters and Headquarters Troop Commander on the battlefield is obsolete since the Forward Support Commander is now located doctrinally at the forward-trains command post.[18] Given the obsolete location, the Headquarters and Headquarters Troop Commander can serve as an ideal cavalry liaison and integrator of multiple staff sections into the reconnaissance plan dependent on being physically located at the BCT command post.[19] Hefti assumes that the obsolete location of the Headquarters and Headquarters Troop Commander relies completely on doctrinal application of the Forward Support Company Commander assuming the forward-trains command post.

Palmer takes the more common approach to the Chief of Reconnaissance by arguing that the Cavalry Squadron Commander is the best candidate because he or she already exercises command authority, is likely the most experienced reconnaissance leader in the BCT, and has access to upper tactical internet removing the requirement to be located with the BCT command post.[20] Palmer's major assumption is the Cavalry Squadron and BCT command posts will have access to upper tactical internet even though a significant planning consideration for units training today is the degradation of

1656 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

communications architecture through enemy electronic warfare employment. Palmer's thesis also assumes that the Cavalry Squadron Commander already has the authority to task all information collection assets within the BCT.[21] This assumption would likely be a point of contention with the Brigade Engineer Battalion who exercises authority over the BCT MICO. Palmer highlights a key point in information collection discussion that "no staff section is in charge of both the planning and execution of information collection" further reinforcing the nature of Army Information Collection as a collaborative effort amongst multiple participants.[22]

Colonel Dwight DuQuensnay and Major Camero Song offer two perspectives on the value that advanced collection management training offers Corps and Division echelons through the auspices of experiences with AIDP-ISR graduates. DuQuensay indicated his experience supervising an AIDP-ISR graduate as the Multi-National Force-Iraq collection manager was able to quickly integrate and synchronize Air Force ISR and Army and contract collection platforms as a "truly joint, aerial ISR force."[23] Drawing on his later Korea experience, DuQuensay likened AIDP-ISR graduates additional collection management experience similar to the planner graduates of the School of Advanced Military Studies.[24] Song, as a graduate of the AIDP-ISR program, highlights the hallmarks of the program as advancing collection management knowledge at the joint task force and national levels which is an important factor in integrating collection platforms.[25] Song further advocates for expanding the AIDP-ISR to the noncommissioned officer corps as well as bolstering all Military Intelligence professional military education on the principles of collection management.[26]

1657 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Institutional and Operational Knowledge Necessary for a BCT CM

The Army provides advanced training in information collection through two skill identifier producing courses at two different centers of excellence. The USAICoE administers the Intelligence, Surveillance, and Reconnaissance (ISR) Synchronization Managers Course or also referred to as the Information Collection Planners Course. This course consists of five weeks of classroom training for military intelligence officers, warrant officers, and non-commissioned officers on skills to serve as a Brigade ISR Planner/Manager and produces the Q7 information collection Planner additional skill identifier.[27] Positions associated with the Q7 additional skill identifier are described as "requiring qualifications in managing the employment of organic and supporting intelligence collection assets, as well as reach back to higher headquarters and intelligence agencies for information, in order to provide the commander with effective intelligence support."[28]

The U.S. Army Armor School administers the Cavalry Leader course at Fort Benning, Georgia for Armor officer and enlisted military occupational specialties. The Cavalry Leader Course produces the C6 additional skill identifier following three weeks of training in the application of reconnaissance and security operations to include "asset synchronization, Cavalry organization employment, synchronization of operations and intelligence analysis, and tactical techniques in a myriad of reconnaissance and security scenarios."[29] The functions associated with the C6 additional skill identifier includes "planning for and employing mounted and dismounted organic assets, employment and integration of various supporting assets including UAS, logistics, Army and Air Force manned aircraft, and SIGINT/MASINT platforms."[30]

1658 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The Defense Intelligence Agency serves as the executive agent for the Certified Collection Management Professional Certification Program while also providing web-based and in-person training on collection management.[31] Likewise, the National Geospatial Intelligence Agency administers the Geospatial Intelligence Professional Certification Program along with associated intelligence discipline specific training.[32] It is also common for intelligence discipline specific courses to include collection management instruction as a means to educate students on how to request collection platforms. Beyond institutional training, the operational force identified training needs amongst the military intelligence force at-large in intelligence synchronization.

An article on the BCT S-2 course by Major Jason Buchanan and Lieutenant Colonel Anthony Covert shows an identified gap in information collection management knowledge in the tactical military intelligence workforce. Summarizing the training efforts to close multiple knowledge gaps, Buchanan and Covert discussed how First Corps, and later the Command and General Staff College, developed a comprehensive training agenda oriented at military intelligence majors and captains.[33] In the model week of training, collection management consists of a full day of training.[34] First Lieutenant Kari LaRubio indicated the need for a BCT collection manager to be knowledgeable in the Shadow UAS that includes the systems capabilities and limitations, briefed by the UAS platoon.[35] This knowledge, in LaRubio's estimation, enables the BCT collection manager to effectively employ the Shadow UAS "within the brigade's reconnaissance plan."[36]

1659 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

How the BCT Doctrinally Executes Information Collection

Three sources of literature provide insight into information collection staffing at the BCT; force management documents, doctrine, and professional discourse. The majority of literature speaks to information collection as a broader team effort versus one individual fulfilling all the functions of collection management.

The definitive force management documentation is the MTOE but unfortunately the current data resides at the official use only-level. Additionally, MTOE data was not available for the brigade or division-level from Operation Desert Storm. More generic Tables of Organization and Equipment provide context to how these organizations were equipped and staffed. Further, the research included the Military Intelligence Battalion organic to the Division for the frame of reference of where the intelligence collection platforms existed during Operation Desert Storm. Intelligence Doctrine active during Operation Desert Storm provides background on intended employment of information collection platforms. To overcome the force management data challenge, doctrine is used to provide context between duty positions and staff proponents through integrating processes. Doctrine from 1986 to 1990 provided context for military intelligence, cavalry, and aviation collection platforms at both the division and brigade-levels. These doctrinal publications included FM 1-111, *Aviation Brigades*; FM 34-10, *Division Intelligence and Electronic Warfare Operations*; and FM 34-80, *Brigade and Battalion Intelligence and Electronic Warfare Operations*.

The Intelligence and Operations doctrine series are the primary contributors to Army information collection doctrine in the form of FM 3-55, *Information Collection*; FM 2-0, *Intelligence*; and Army Techniques Publication (ATP) 2-01, *Plan Requirements*

1660 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

and Assess Collection. Maneuver doctrine supports information collection through ATP 3-20.96, *Cavalry* Squadron; FM 3-04, *Army* Aviation; FM 3-90-2, *Reconnaissance, Security and Tactical Enabling Tasks*; FM 3-98, *Reconnaissance and Security Operations*; and FM 3-96, *Brigade Combat Team*. Joint publications commonly use the term ISR where the Army uses information collection to describe the same activity. Joint Publication 2-0 defines ISR as "an activity that synchronizes and integrates the planning and operation of sensors, assets, and processing, exploitation, and dissemination systems in direct support of current and future operations…this is an integrated intelligence and operations function."[37] This definition is identical to the Army definition of information collection presented earlier where there is no clear indicator why the terms are different.

Doctrine informs that Information Collection is a collaborative process of activities and tasks. Information collection consists of planning requirements and assessing collection, tasking and directing collection, and executing collection; which will be referred to as components since doctrine does not define if these are tasks, activities, or the overall process.[38] Information collection activities connect the components of information collection with staff responsibility, (see figure 1).[39]

FM 3-55 identifies staff roles and collaboration responsibilities for the information collection activities. Planning requirements and assessing collection are associated with the intelligence staff collaborating with the rest of the unit staff.[40] Tasking and direction belong under the purview of the operations officer, supported through the operations staff.[41] Information collection tasks and operations are categorized as reconnaissance, surveillance, security operations and intelligence operations.[42] FM 3-55 also establishes the concept of the situationally needed, Operations and Intelligence

1661 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Working Group. This working group represents an amalgamation of staff sections whose purpose is "coordination and integration of information collection activity and provide recommendations to the commander."[43]

Conversely, FM 2-0 identifies information collection tasks as collection management, direct information collection, execute collection, and conduct intelligence-related missions and operations.[44] FM 2-0 further states that the intelligence warfighting function contributes to all tasks except execute collection.[45] Executing collection rests with the respective units carrying out the collection tasks of reconnaissance, surveillance, security and intelligence operations. FM 2-0 assumes the responsibility of collection management with the supporting tasks of develop requirements, develop collection management tools, assess collection, and update collection management tools.[46] Figure 1 below shows the connection between FM 3-55's information collection activities and FM 2-0's collection management tasks as intelligence staff functions.

1662 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

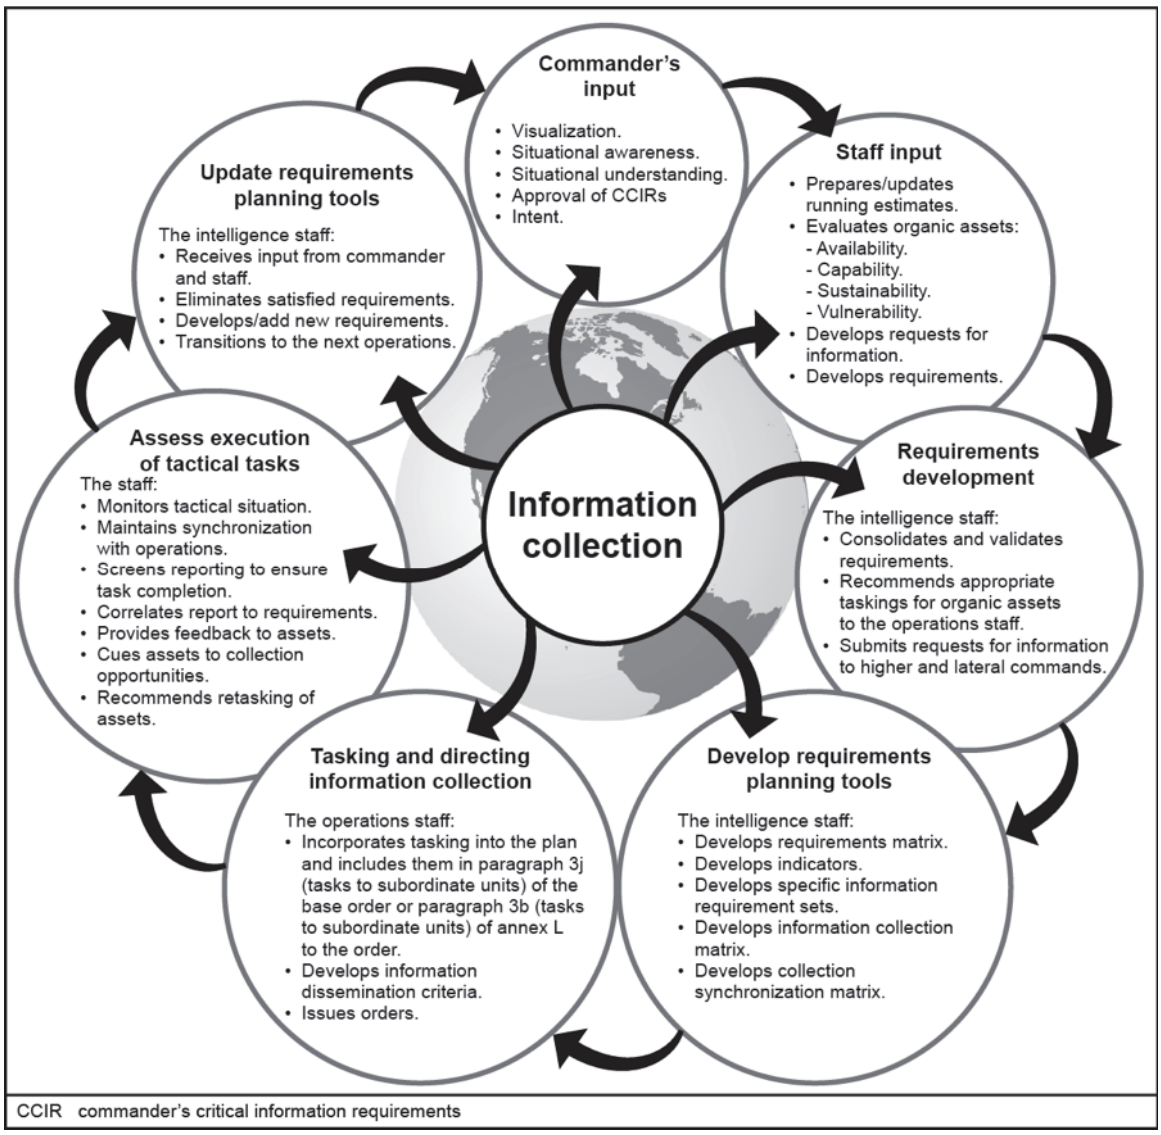

Figure 1. Information Collection Activities

Source: Headquarters, Department of the Army, Field Manual 3-55, *Information Collection* (Washington, DC: Government Printing Office, May 2013), 1-4.

ATP 2-01 serves as the intelligence series publication to further refine the intelligence warfighting functions role for information collection activities. ATP 2-01 identifies conflicting information collection tasks with FM 2-0 in the form of "plan requirements and assess collection, task and direct collection, and execute collection."[47]

1663 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

In this case, ATP 2-01 mirrors FM 3-55 with the exception that FM 3-55 does not specifically call these tasks.

FMs 3-98, *Reconnaissance and Security Operations*, and 3-90-2, *Reconnaissance, Security and Tactical Enabling Tasks* provide similar descriptions of the responsibilities for information collection at the BCT. The primary focus of these FMs is on the reconnaissance assets, namely the BCT Cavalry Squadron. One major distinction presented is the concept of the BCT Reconnaissance Cell that is not mirrored in any of the other doctrine publications. FM 3-98 further does not discuss how a BCT Reconnaissance Cell works within the context of the Operations and Intelligence Working Group that is mentioned in virtually all of the doctrine publications, except FM 3-0, FM 3-90-2 and FM 3-96. FM 3-98 indicates the purpose of the Brigade Reconnaissance Cell fulfills the employment of sensors and assets part of the information collection definition by "coordinating and synchronizing the BCT's reconnaissance operations."[48] Not directly stated, the intent of the BCT Reconnaissance Cell appears to serve an enduring function of staff coordination with a smaller cadre of staff members including S-2, S-3 Plans, Brigade Aviation Element, Tactical Air Control Party, and Fire Support Coordinator.[49] This cell differs from the often mentioned Operations and Intelligence Working Group because the working group is characterized as a "ad hoc" group focused on information collection planning which is the first part of the information collection definition.[50]

Finally, leaders writing about observations and experiences in various positions regarding information collection at the BCT provides context to in how information collection is managed and varies between BCTs. In Lobdell's article, she mentions that

1664 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

even though the previously mentioned Operations and Intelligence Working Group at the BCT and Battalion levels is optional, it does not diminish the need for close coordination between the S-2 and S-3.[51]

The concept of staff relationships to support information collection appeared multiple times. LaRubio shared insights on the interactions between BCT staff and the tactical UAS platoon. LaRubio introduced the Brigade Aviation Element as an important participant in the BCT's information collection operations with a variety of capabilities.[52] LaRubio's conclusion reinforced the common theme of relationships between staff and maneuver elements involved in information collection.[53]

The importance of relationships is the central argument in Chief Warrant Officer Two David Pierce's article on integrating the BCT S-2 and Military Intelligence Company (MICO). Pierce's assertion of relationships and early integration are important to the information collection discussion as the MICO resources are currently located under the Brigade Engineer Battalion for mission command with their operational design being the bulk of the Brigade's intelligence warfighting function workforce.[54]

Three Decades of Collection Platform Development at the BCT

The last thirty years have seen significant growth in collection platform capabilities at the tactical level. This tactical growth extends beyond the introduction and fielding of UAS to the Brigade and Battalion echelons. The transition of collection platforms in brigades that occurred included structural changes such as the Brigade Reconnaissance Troop during the Force XXI era. The Brigade Reconnaissance Troop, predating the BCT, developed from a reduction in battalion scout formations to create a reconnaissance force organic to the brigade to address a known gap in capability.[55] Major

1665 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Todd Poindexter's thesis analyzed the development of cavalry capability at echelon over time and is shown in figure 2 below. The later transition to the BCT brought a cavalry squadron of platoons equipped with combat vehicles and many, depending on the type of BCT, outfitted with the Long-Range Scout Surveillance Systems. The Long-Range Scout Surveillance System at the BCT extended the range that scouts could observe significantly over the analog alternative of binoculars. The integration of military intelligence collection platforms in the MICO brought UAS, signals intelligence collectors, and human intelligence collectors to the BCT as well. This diversity of collection platforms in the BCT created a true ISR capability organic to the BCT.

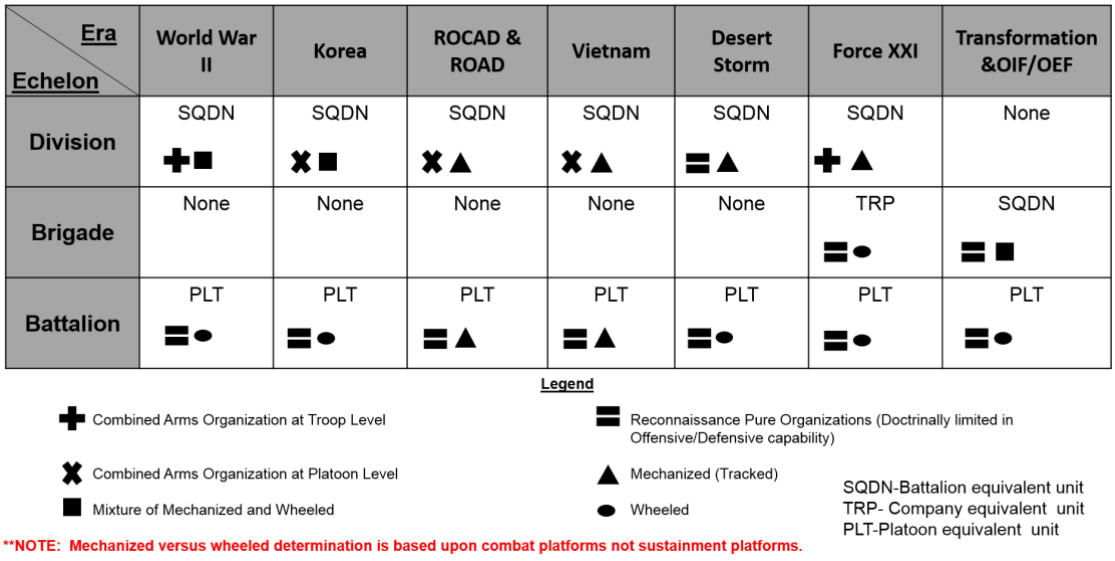

Figure 2. Example of Collection Platform Transition

Poindexter, "Transforming Mechanized Reconnaissance: How the Armored Brigade Combat Team (ABCT) Cavalry Squadron Should Be Structured For Reconnaissance and Security Operations in the near Future" (Master's Thesis, U.S. Army Command and General Staff College, Ft. Leavenworth, KS, 2014), 68.

1666 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Several articles allude to how Operations Enduring Freedom and Iraqi Freedom influenced tactical-level information collection. The professionally accepted opinion is that prolonged rotational deployments in Iraq and Afghanistan created an over-reliance on theater collection platforms, particularly aerial.[56] The manifestation of this reliance is the lack of detailed planning for information collection assets by scheduling long blocks of collection on the Information Collection Synchronization Matrix and approaching collection dynamically.

Discussions of the BCT Collection Manager

Primarily, the literature shows doctrinal and experiential recommendations on how to most effectively employ information collection with the existing BCT force structure. No author addressed or attempted to explain why the BCT is not authorized a collection manager. Three authors addressed expanding collection manager skills to the BCT and spanned recommendations from expanding the existing AIDP-ISR program to non-commissioned officers, assign dedicated officers for ISR, and pass the responsibility to a combat arms officer supported by a subordinate military intelligence officer.[57] This recommendation came without calling for a position at the BCT but understanding that the majority of non-commissioned officers trained to the AIDP-ISR-level would serve at the BCT.

Within doctrine, there is mixed discussion of the position of the collection manager spread through a variety of publications. The collection manager is typically mentioned in one of three capacities; in Army, Joint, or generic. The preponderance of reference to the collection manager in Army doctrine was in an Army capacity. These references came in ATP 2-01, *Plan Requirements and Assess Collection*; FM 2-0,

1667 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Intelligence; FM 3-55, *Information Collection*; ATP 3-60, *Targeting*; and ATP 6-0.5, *Command Post Organization and Operations*. The most references to the collection manager came in ATP 3-60, *Targeting*, that describes the role of the collection manager in assessing the information collection plan against systems supporting targeting and focusing on "high payoff targets that cannot be covered with available assets."[58] Curiously, the collection manager was not mentioned in ADP 2-0, *Intelligence*; and ATP 2-01.3, *Intelligence Preparation of the Battlefield*. Nor was the position mentioned in the operations series manuals of FM 3-96, *Brigade Combat Team*; FM 3-98, *Reconnaissance and Security Operations;* or FM 3-90-2, *Reconnaissance, Security, and Tactical Enabling Tasks*.

Several authors discussed the importance of the BCT collection manager without specifically mentioning a single duty position. Sterioti highlights the importance of the role the collection manager plays to building shared understanding and recommends that a properly trained officer or noncommissioned officer is critical to successful information collection operations.[59] LaRubio argues that the "Brigade information collection Manager is coordinating the eyes and ears of the BCT commander's assets"[60] further qualifying the position as requiring "continual planning and changes as the mission changes."[61] This is an example of the importance of the BCT collection manager as a duty position.

Fighting for Intelligence or Information

Lobdell highlights how the new FM 2-0 reframes intelligence operations as part of the "fight for intelligence."[62] Lobdell describes "fighting for intelligence" as an old term renewed to conjure a mental model of the contested nature of ground combat in

1668 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

LSCO, while reiterating the complexity of the multi-domain environment and capable threat profile.[63] Information collection plays a prominent role in the identified "key aspects of fighting for intelligence" with three of the six directly associated with the information collection plan and an additional nod to the importance of effective staff integration.[64]

Similarly, Lieutenant Colonel Nathan Palisca offered a cavalry perspective via defining the "Fight for Information."[65] Palisca's argument focused on formally defining the term with key stipulations of information collection with synchronized platforms in contact with an enemy, emphasizing the eight forms of contact.[66] Just like Lobdell, Palisca seeks to integrate information collection in the context of LSCO. Ultimately, both Lobdell and Palisca discuss the necessary doctrinal and institutional changes necessary to shift away from the counter-insurgency mindset that has dominated information collection over the last seventeen years.

Literature Review Summary

Ultimately there is no shortage of professional commentary on the challenges units face in conducting information collection. The challenge for Army units to manage information collection grows as the capabilities increase with de-synchronized guidance from doctrine emerging from two centers of excellence. Both the Army Intelligence and Maneuver communities indicate that there are challenges with both developing unique, and sometimes sweeping, recommendations to address the deficiencies.

CHAPTER 3

RESEARCH METHODOLOGY

Qualitative Content Analysis Overview

The research approach employed in this thesis is a qualitative document and narrative content analysis utilizing categorization and coding to determine the value of an authorized collection manager on the BCT MTOE as derived from professional opinions and experiences. The analysis focuses on data from a variety of professional discourse covering information collection doctrine, training, and experiences. Qualitative content analysis is ideal for this research because of the breadth of professional writing about improving U.S. Army information collection. There was no data found in a format to support effective quantitative analysis such as human subjects research surveys of leaders and Soldiers on U.S. Army information collection. The content analysis approach lends to an effective way to extract inferences and meaning in professional writing from a wide variety of authors perspectives. Dr. Steve Stemler's "Overview of Content Analysis" in the Journal *Practical Assessment, Research &* Evaluation served as the seminal source for developing this research methodology.[1]

Research information was obtained through historical searches of military professional publications, primarily U.S. Army centers of excellence, with additional searches conducted on joint military professional periodicals. The figure below shows the research process employed to answer the fundamental research question of determining the value of a MTOE BCT collection manager. (see figure 2). Specifically, two periodicals representing the intelligence and maneuver centers of excellence provided the bulk of the professional writing. The *Military Intelligence Professional Bulletin* serves as

1674 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the quarterly forum for U.S. Army Intelligence professional discussion. The *Armor Mounted Maneuver Magazine* represents the U.S. Army reconnaissance community through the maneuver warfighting function. The content analysis supports the research question through the wide variety of perspectives collected. The supporting research questions are minimally supported by the methodology as they are largely answered through the literature review. The professional writing represents a unique perspective and experience from each author in different organizations and in different capacities all focused on improving information collection. Professional discourse falls under two categories of data in this research.[2] The first represents professional writing that directly relates to information collection at the BCT. The second represents professional writing that relates to information collection in general.

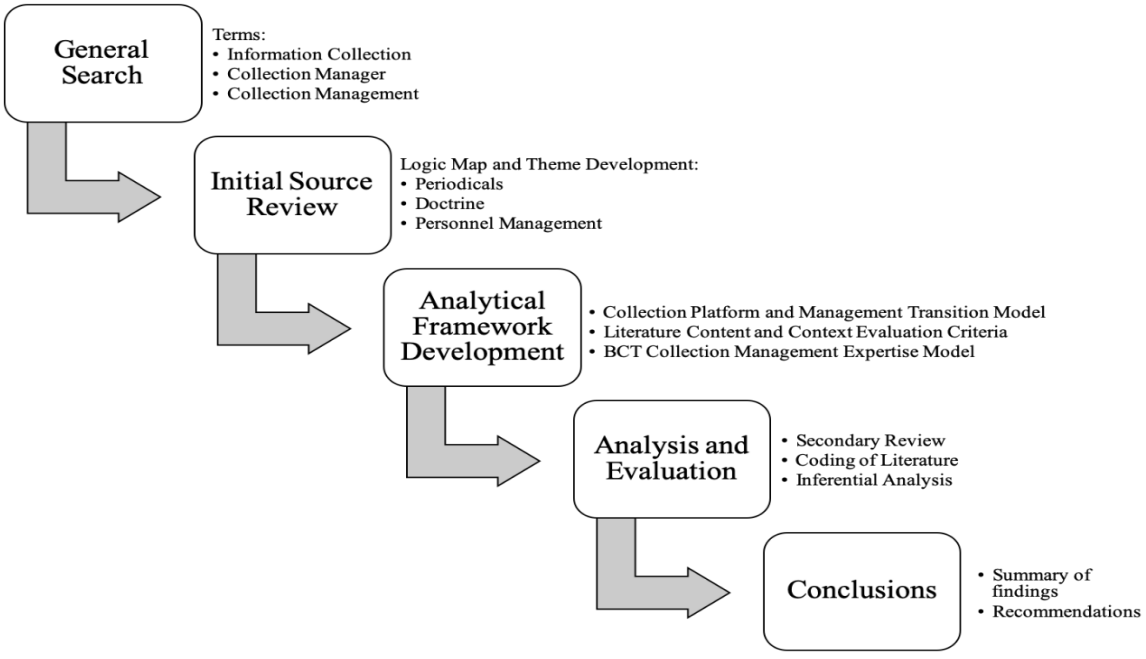

Figure 3. BCT Collection Manager Research Process

Source: Created by author.

1675 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Coding is based on *a priori* categorization of qualities necessary for a BCT collection manager, (see figure 4).[3] The dependent variable for analysis is the BCT collection manager, annotated in the black square. The independent variables for qualitative analysis derive from the themes identified within the research as well as professional experience in the form of collection management processes, information collection tools, and information collection systems, annotated as white ovals (see figure 4). Essentially, the analytical framework was developed as a mind map from personal experience of twelve months of formal collection management training and grouped into categories of common themes identified from the research literature. Together, these variables provide the analytical framework to determine the value of a MTOE authorized collection manager in the BCT. The gray blocks within the analytical framework represents the component parts of each category theme. In several cases, these component parts consist of additional entities too detailed to graphically represent, but further explained below.

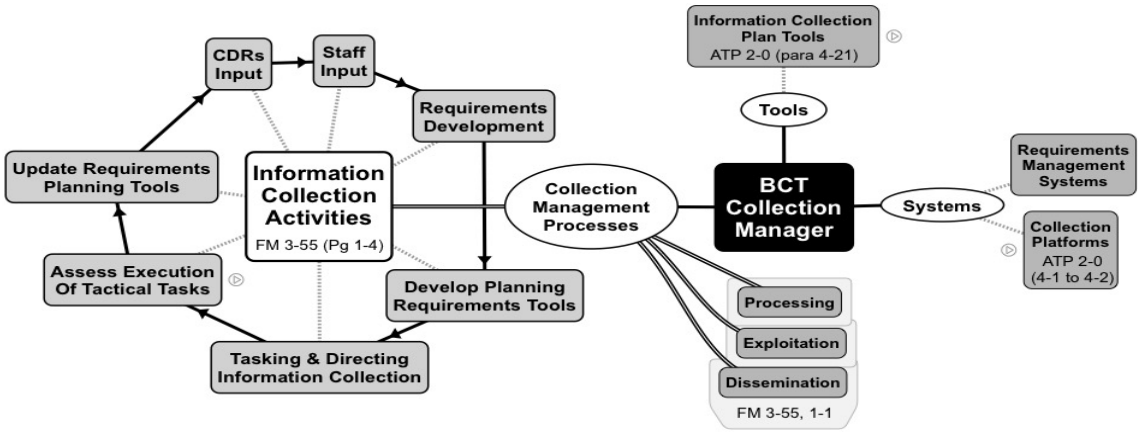

Figure 4. BCT Collection Manager Logic Map

Source: Created by author.

1676 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The analytical framework began with knowledge and skills of the collection management processes which is a combination of the Information Collection Activities and the definition of Army information collection from doctrine. The Information Collection Activities clearly include the essential concepts of planning and employment of sensors and assets as the information collection definition states. The next quality is knowledge and skills of tools associated with information collection. These tools are doctrinally defined as the Information Collection Matrix, Information Collection Synchronization Matrix, Information Collection Overlay, and the Information Collection Annex to the Order. The final quality of a collection manager is divided into knowledge and skills of collection systems inclusive of the collection platforms and the requirements management systems for requesting collection platforms. Knowledge of collection platform capabilities includes both assigned equipment and platforms at higher echelon.

Transition of Collection Platforms and Management

Collection platforms have diversified and transitioned over the last thirty years since Operation Desert Storm where collection management personnel and expertise has not. To show this transition, a comparison is used of collection platforms and collection management roles at echelon during Operation Desert Storm and present BCT constructs (see table 1). Overall aggregated collection platform numbers are used to maintain the content at the unclassified level. For this table, a collection platform is considered a single signals intelligence sensor, a human intelligence collection team, a ground scout platoon, attack or reconnaissance aviation platoon, and the ground control station for UAS. The ground control station is the limiting factor for UAS since a unit may only operate as many UAS aircraft as they have ground control stations, such as six RQ-7

1677 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Shadows may be limited to three ground control stations. The echelon relationship is defined based on an assigned and typical operational control status. For example, the Division had an assigned Military Intelligence Battalion and Cavalry Squadron during Operation Desert Storm timeframe. Conversely, the current BCT structure has an assigned Cavalry Squadron and separate Engineer Battalion where the MICO is located.

Collection management roles are qualified as staff or units intended to fulfill collection management. The staff or units associated with collection management functions are identified by the joint collection management function they provide, such as CRM, COM, or CMM. Although this research is focused on the management of BCT organic collection platforms, it is necessary to acknowledge that a component of collection operations management is requesting higher-level collection platforms when organic capabilities are not available. This could be requesting a UAS capable of operating deeper in the area of operations or a collection platform providing an intelligence discipline capability not organic to the BCT. As if managing organic platforms was not challenging enough, the addition of requesting and managing collection operations of non-organic platforms can drastically increase the complexity of collection management, to say nothing of the reality that requesting capabilities requires a thorough knowledge of the capability, as well as the processing, exploitation, and dissemination requirements to make collection timely. The requesting of higher-level collection platforms as a component of collection operations management is deliberately excluded from this research as the context of LSCO presumes the availability of higher-level collection platforms for subordinate units' requests will be limited. The notion of limited request-able collection platforms is a departure from the experiences of many

1678 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

units who grew accustomed to the ISR soak in Operations Enduring Freedom and Iraqi Freedom.

Table 1. Collection Platform and Management Transition Model

Echelon	Era / Resource	Pre-Operation Desert Storm (1986-1990)	Modular BCT (2003-Present)
Division	Collection Platforms	Aggregate Quantity of Scout Platoons, Air Cavalry Platoons, Attack Aviation Platoons, and UAS ground control stations, SIGINT sensors, and HUMINT collection teams	
	CM Roles	Staff or Unit Organizations by joint collection management function	
Brigade	Collection Platforms	Aggregate Quantity of Scout Platoons, Air Cavalry Platoons, Attack Aviation Platoons, and UAS ground control stations, SIGINT sensors, and HUMINT collection teams	
	CM Roles	Staff or Unit Organizations by joint collection management function	

Source: Created by author.

The source data for analyzing collection platform and management transition came from Tables of Organization and Equipment for a Heavy Division in 1986 as well as current Army doctrine and additional skill identifier descriptions. Military Intelligence (Combat Electronic Warfare and Intelligence) Battalions as of 1986 were equipped with both collection and jamming capabilities. The analysis focuses on the collection capabilities and excludes jamming systems. The Brigade collection platforms during 1986 assumes the assigned maneuver battalions maintain operational control of their assigned scout platoons. The analysis of the pre-Operation Desert Storm Division focuses on the heavy division assuming there is more collection platform capability than light or

1679 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

airborne divisions. The current organic BCT capabilities are the total number of information collection platforms represented by the Cavalry Squadron and the MICO. Further, the analysis limits UAS consideration to the Shadow, RQ-7B, tactical UAS aircraft. This limit results in the exclusion of the Raven, Small UAS, that is fielded at the company and platoon level. This exclusion regards the Raven as a company and platoon-level platform versus the Shadow as a BCT-level platform. If the Raven was factored in, the numerical platforms at the Brigade level would certainly increase. Further, the chemical reconnaissance platoon within the brigade engineer battalion is not included as it is generally focused on the chemical threat.

Determining the Value of the Collection Manager

The key to determine the value of the collection manager requires analysis of written material against the identified themes from the literature related to how the material relates to the position of the collection manager. Each of the three major themes identified are valued against how the document or narrative relates to the collection manager by directly relating to the BCT collection manager, relating to the collection manager generically, or relating to collection management in general (see table 2). The literature evaluation criteria are limited to the professional writing from the *Military Intelligence Professional Bulletin* and *Armor Mounted Maneuver Journal*, as doctrinal references to the collection manager are reflected in the word count analysis. In total, fifteen articles serve as the data set for analysis with seven from the *Military Intelligence Professional Bulletin* and eight from *Armor Mounted Maneuver Journal*.

Table 2. Literature Evaluation Criteria			
Literature theme derived framework content valuation:			
	Collection Management Processes Information Collection Tools Information Collection Systems		
Author	Discussion directly related to a BCT Collection Manager	Discussion generically related to a Collection Manager	Discussion related to information collection generically
Context Valuation			
Author	Single perspective of multiple direct observations or experiences	Multiple perspective direct observation or experience	Single perspective direct observation or experience

Source: Created by author.

The literature evaluation criteria identified in table 2 is not intended to grade the professional recommendations as good or bad. The evaluation criteria are intended to show how the role of the collection manager relates to the identified themes from the literature and thesis. This evaluation is necessary as no literature clearly identified a MTOE collection manager at the BCT as a recommendation for improving Army information collection. Likewise, the context valuation is designed to show which perspectives on information collection are formed from a single observation or experience, such as performing the position, from the perspective of a combat training

1681 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

center trainer with multiple direct observations over a period of time. Neither the content nor the context valuations intend to diminish the value of the opinions represented by the authors.

Collection Management Expertise in the BCT

The final method of analysis looks at the intended distribution of advanced collection management training within the BCT. The purpose of analyzing personnel management documents is to determine where positions are associated with advanced information collection training at the BCT level. The BCT level, in this analysis, focuses on positions associated with a BCT collection platform. This analysis intends to show the density of positions coded for either the Q7, Information Collection Planners Course graduate, or C6, Cavalry Leader Course graduate, additional skill identifiers (see table 3). Advanced training in collection management is annotated as the number of C6 and Q7 ASIs based on tables 4-3 and 12-2 of Department of the Army Pamphlet 611-21, *Military Occupational Classification and Structure*.

Methodology Summary

The three analytical approaches identified allow for a comprehensive document and narrative analysis to show common themes as they relate to the role of the collection manager, specifically at the BCT. Additionally, the different analytical approaches allow for each type of data to be evaluated against unique criteria. Finally, the use of multiple approaches with different criteria allows the inference of relationships between doctrine, professional writing, and force management documents.

CHAPTER 4

ANALYSIS

This research analyzes doctrine and professional writing from military intelligence and cavalry perspectives to determine the value of an authorized MTOE position for a BCT collection manager through the variables of collection management processes, information collection tools, and information collection systems. This analysis is accomplished through examining the transition of collection platforms over the last thirty years; content analysis of professional writing as it relates to the BCT collection manager and information collection in general; and the comparison of existing information collection management expertise in the BCT.

Collection Platforms and Management: Past and Present

Analysis of the Heavy Division Table of Organization and Equipment and doctrine from 1986 revealed a multitude of collection platforms located within the Military Intelligence Battalion and Cavalry Squadron. The Military Intelligence Battalion contributed twenty-eight of the pre-Operation Desert Storm collection platforms. These platforms included an array of ground-based communications intelligence, ground-based electronic intelligence, ground surveillance radar, and long-range surveillance teams.[1] The divisional cavalry organization of 1988 consisted of two troops of three platoons for a division total of six reconnaissance platoons that doctrinally existed in the Heavy Division Aviation Brigade.[2] The Operation Desert Storm Era Aviation Brigade for a heavy division included a cavalry squadron and two attack helicopter battalions. The Cavalry Squadron adds an additional total of four platoons of AH-1 Cobra and OH-58

1684 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Kiowa helicopters.[3] The Attack Helicopter Battalions provide a total of six more platoons consisting of a mix of OH-58 Kiowa and AH-64 Apache aircraft.[4] In 1986, the Division Intelligence Section supported the Division Tactical Operations Center Support Element with a staffed Collection Management and Dissemination (CM&D) Section.[5] The CM&D Section was responsible for mission management that included "collection planning, tasking, and coordination" as well as "dissemination of combat information and intelligence."[6] FM 34-10 stipulates that the collection planning "converts priority intelligence requirements and information requirements into collection missions."[7] This function demonstrates that the division maintained a dedicated team of collection managers to fulfill what is now considered by joint doctrine as COM and CMM.

Current doctrinal division information collection capabilities exist entirely from the Combat Aviation Brigade. This is not to say that the Division Commander is incapable of composing a ground reconnaissance force, but more so highlights that the Division Cavalry Squadron of the Operation Desert Storm era no longer exist, as evident from Poindexter's diagram of reconnaissance capability by echelon by era mentioned in chapter two.[8] Certainly, the Division Commander can task a subordinate BCT, as in the case of 1st Stryker Brigade Combat Team, 4th Infantry Division, as a Reconnaissance and Security BCT or a subordinate BCT's cavalry squadron.[9] A healthy debate exists on how to fill the ground reconnaissance capability at the division-level considering that no dedicated division cavalry formation currently exists and certainly exceeds the scope of this research. This research focuses on the current doctrinal role of the Combat Aviation Brigade as a division capability with the first core competency being "provide accurate and timely information collection."[10] The Division's reliance on the Combat Aviation

1685 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Brigade for primary information collection capability is evident from the organizational structure of the Combat Aviation Brigade.

The Combat Aviation Brigade maintains an Aerial Reconnaissance Squadron of twenty-four AH-64 Apache helicopters organized with twelve RQ-7 Shadow UASs. The Attack Reconnaissance Battalion consists of twenty-four AH-64 Apache helicopters with an additional company of twelve MQ-1C Gray Eagle UAS. These MQ-1C Gray Eagle UAS are often reserved for divisional control as dedicated collection platforms.[11] The key distinction between the MQ-1C Gray Eagles and the RQ-7 Shadows within the Combat Aviation Brigade lies in the fact that the RQ-7 Shadows are integrated into the Attack Reconnaissance Squadron Troops whereas the MQ-1C Gray Eagles operate as a separate company within the Attack Reconnaissance Battalion.[12] Further, Michael Brake discusses a limiting factor for UAS in his 2004 article on "BCT Intelligence Operations" where the capability of the UAS depends on the number of ground control stations as opposed to the number of aircraft. Using Brake's description of the proposed BCT MICO, this research considers half of the number of UAS as operational at any one time considering there were roughly half the number of ground control stations proposed in 2004.[13] Therefore, the operational total of UAS in the division Combat Aviation Brigade is considered to be six RQ-7 Shadows and six MQ-1C Gray Eagle UASs. The key point for the division echelon is, barring the deliberate tasking of a subordinate BCT to provide forces for information collection, the division relies primarily on the Combat Aviation Brigade for all organic information collection capabilities. The division G-2 maintains a collection management element led by a Major, as evident from the AIDP-ISR program

1686 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

who executes COM functions as well as referenced in FM 3-55, *Information Collection*.[14]

The Brigade echelon shows a significant difference in capability between the Operation Desert Storm and current BCT eras. Prior to and through Operation Desert Storm, the brigade echelon did not have any dedicated reconnaissance capability, as Poindexter's figure indicated in chapter two.[15] Similarly, FM 34-80, *Brigade and Battalion Intelligence and Electronic Warfare Operations*, provides a very generic description of the intelligence and electronic warfare capability at the Brigade level as the maneuver battalions.[16] Divisional MI BN doctrine serves as a nod to the modularity of the BCT era with conceptual employment of task-organized MI company-teams in a direct or general support role to subordinate brigades.[17] The supporting MI company-team explains why the Brigade maintained a management role over MI platforms through the Battlefield Information Control Center (BICC) even though the Brigade had no organic or permanently assigned platforms.

According to FM 34-80, *Brigade and Battalion Intelligence and Electronic Warfare Operations*, the S-2 was responsible for the reconnaissance and security plan "as the formal collection management tool" supported through the BICC.[18] The BICC fulfilled responsibilities similar to the current Brigade Intelligence Support Element through developing intelligence requirements, the reconnaissance and security plan, and then executing the approved plan.[19] In essence, the BICC served all roles of CRM, COM, and CMM much like a miniature analysis and control element coupled with a current operations element. The key takeaway here is no specific position beyond the Brigade S-

1687 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

2 is identified as responsible for collection management in the pre-Operation Desert Storm brigade.

Current BCT collection capabilities, both platforms and management responsibilities are difficult to provide in an unclassified setting. Definitive information for numbers of collection platforms and personnel in management roles exists at the official use only level through MTOEs and generically through doctrine. For this research, Brake's article on the proposed BCT MICO provides enough information for overall consideration of capabilities. Without providing the specific numbers of each MI platform, the BCT MICO provides eight collection platforms while the Cavalry Squadron contributes six total reconnaissance platoons.[20] The current Cavalry Squadron consists of three reconnaissance troops of two platoons with an additional tank company. This tank company contributes an additional three platoons presuming a hunter-killer capacity when employed with the Cavalry Squadron. Another application of the tank company in the Cavalry Squadron is serving as a brigade reserve which would reduce the overall platform count by three.

Collection management responsibilities in the current BCT vary widely depending on the source documentation. Brake mentions ISR synchronization and requirements management as responsibilities for the MICO's analysis and integration platoon, which exists now as the information collection platoon.[21] FM 3-98, *Reconnaissance and Security Operations*, discusses the previously mentioned Brigade Reconnaissance Cell which performs COM responsibilities by "allocate[ing] organic, attached, and supporting assets and enablers against the [named areas of interest] to ensure seamless and in-depth reconnaissance operations."[22] The Operations and

1688 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Intelligence Working Group mentioned in both ATP 2-01, *Plan Requirements and Assess Collection*, and FM 3-55, *Information Collection*, is designed to "achieve a fully synchronized and integrated information collection plan" through "validat[ing] information requirements and deconflict the use of organic and attached assets."[23] Regardless of echelon, doctrine states the O&I WG is a temporary group for the sole purpose of information collection integration and coordination.[24] A fair argument can be made that the Cavalry Squadron staff itself is a collection management organization through the functions of CRM, COM, and CMM.

The development of the BCT clearly shows how the organic collection platforms available to the brigade and BCT changed over the last three decades, speaking to supporting research question two, (See table 4). This is evident by the clear increase in BCT collection platforms with a corresponding decrease in Division collection platforms that mostly represents Military Intelligence platforms followed by Reconnaissance Platoons. This transition also provides insight on how the brigade-level was and is designed for information collection, which speaks to supporting research question one. Doctrine shows that collection management responsibility rested with the Brigade S-2, and in many ways still exists today. However, current doctrine indicates that many representatives from other warfighting functions are involved in information collection management.

Source: Created by author.

The collection platform data is pretty clear that information collection platforms increased at the BCT level. What is less clear is who is responsible for the collection management at the BCT considering the data reflects four staff units or organizations capable of fulfilling collection management functions. From FM 2-0, collection management related responsibilities of the S-2 section are:

> Developing collection strategies; overseeing the intelligence cell's contributions to collection management; coordinating requirements with higher, lateral, and subordinate units; ensuring ongoing intelligence operations are collecting

1690 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

> information needed for anticipated decisions; and recommending changes to the information collection plan based on changes in the situation or weather.[25]

Of the aforementioned tasks, each can be categorized as a function of either CRM or COM with the key takeaway being that collection management functions do reside in the S-2 section, which applies at all echelons with an intelligence section. Battalion S-2s provide CRM for their formations, including submitting requests to the BCT for support, and COM of organic and attached collection platforms. The cavalry squadron S-2, as part of the squadron staff, identified in table 4 above, provides significant CRM functions to BCT collection platforms as the cavalry squadron typically crosses the line of departure well before any operations order is finalized, and in many instances, before the information collection plan is finished. From previous discussion in chapter two, the Brigade Reconnaissance Cell and the Operations and Intelligence Working Group are ad-hoc organizations composed of members with primary responsibilities and only when necessary. This temporary basis poses challenges in the large-scale combat operations environment since most leaders will likely be focused on their primary duties. This focus would presumably make gathering the right leaders together to effectively compose a Brigade Reconnaissance Cell or Operations and Intelligence Working Group. Conversely the information collection platoon and the cavalry squadron staff are permanent organizations, but each is limited in capability to provide collection management functions as they are doctrinally organized. The information collection platoon does not have CMM authority over any of the military intelligence collection platforms. The cavalry squadron staff does not have CMM either unless the military intelligence company is task organized under the cavalry squadron. Acknowledging the lack of a dedicated primary duty collection management responsibility, this research looks to the

1691 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

professional contributions from leaders within the Army maneuver and intelligence communities for insight in how units approach information collection management.

The Value of the Collection Manager

The professional writing in the *Military Intelligence Professional Bulletin* and *Armor Mounted Maneuver Journal* provides insights into how units are approaching information collection within the force. These perspectives are grounded in direct observations or experiences by the authors. Seventeen total articles covering tactical information collection spanning thirty years were evaluated on both content and context, (see table 5). Four of the seventeen articles directly related to a BCT collection manager when discussing the analytical variables of collection management processes, tools, and systems. An additional five articles referenced the BCT collection manager in one of the analytical variables. Of note, not all of the discussions highlighted things that collection managers do well or that units do well with regard to information collection. On the contrary, most articles focused on missing capabilities and skills while presenting possible solutions that span the range of doctrine, organization, training, material, leadership education, and personnel. Throughout the articles, three key points stood out as they relate to information collection and the analytical variables of collection management processes, tools, and systems. These three points are: information collection is a team effort; information collection leaders must know the capabilities and architecture; and most importantly, the purpose of information collection is to support the commander's decision making.

Information Collection is a Team Effort

No authors attempted to argue that a one-person operation could successfully integrate information collection platforms into the information collection plan. Ten of the

1693 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

seventeen articles directly addressed the integration of the intelligence warfighting function with other warfighting functions as a necessary component of successful information collection operations. These observations varied in perspective and emphasis but collectively drive to the same point; that integration is key but the leader of the effort matters. The secondary point inferred is that the lack of integration results in divergent, unsynchronized plans of maneuver and intelligence warfighting function collection platforms. The clearest example of describing the lack of integration is the frequent use of the term synchronization. Synchronization appears in most of the articles and refers collectively to the integration of multiple platforms in time and space with the overall BCT operation. As Adams described it, "failure to use information collection planning as an integrating process for multiple staff members risks wasting precious resources or missed opportunities."[26] The last contribution of the team effort approach is how units define or align collection management functions with personnel in the BCT. The frequent association of collection management functions without calling them a collection manager is represented in the Chief of Reconnaissance concept.

Palmer highlighted that no single staff section owns the "planning and execution of information collection" further elaborating on a list of personnel; the "S-2, S-3, information collection manager, cavalry squadron, military intelligence company, attached aviation units and attached UAS all have a major role in the information collection process."[27] LaRubio also includes the Brigade Aviation Element and the Staff Weather Officer as critical staff members for coordination.[28] Integration goes beyond staff members at the brigade-echelon as evident from several authors indicating coordination between echelons was critical. This point was echoed by Palisca in that the

1694 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

"cavalry squadron S-2 and S-3 must maintain a continual dialogue with the BCT S-2 and S-3."[29] Likewise, Sterioti mentions the cross-echelon coordination to identify gaps and ensure understanding between priority intelligence requirements, named areas of interest, and the event template.[30] Childs and Stertori both addressed the importance of the information collection rehearsal with Childs offering multiple combat training center observations of units failing to rehearse the information collection plan. Childs perspective of responsibilities mirrors current doctrine with the BCT S-3 or Chief of Reconnaissance chairing the information collection rehearsal with the BCT collection manager leading the rehearsal.[31] Sterioti further recommends that the intelligence warfighting function collection manager needs a "counterpart" in the BCT current operations cell who understand the plan and the platforms as continuity across the staff.[32] This larger team approach necessitates the question of who is in charge?

The easy and often default answer is the commander who does so through planning and reconnaissance guidance which Kuderka and Eickbush observed failures of commanders to drive the information requirement process.[33] Armstrong echoed the need for commander's guidance beyond how to employ the UAS.[34] Beyond the commander's role, most authors echo doctrine with the S-3 serving as the orders issuing authority and the S-2 providing the majority of planning tools to the collection plan. Doctrine presents the S-3 as the integrating authority for the information collection effort through the operations and intelligence working group, BCT reconnaissance cell, and the orders process for annex L, *Information Collection*. Kuderka and Eickbush elaborate that observations at the combat training centers extend to failures of operations staffs to fill

1695 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the doctrinal information collection integration role by leaving the process to the battalion S-2.[35]

Two authors approached the integration problem through the lens of effective rehearsals. Childs and Armstrong both recognized that a separate information collection rehearsal was necessary as a synchronization tool following integrated planning. Childs recommends that the information collection rehearsal is conducted prior to the BCT combined arms rehearsal.[36] Ultimately both Childs and Armstrong focus on executing a rehearsal that provides a clear shared understanding and identifies intelligence gaps.[37] The key consideration for Childs and Armstrong's perspective is through observations from combat training center rotations where units have dedicated time to conduct planning prior to crossing the line of departure. Effective information collection rehearsal becomes significantly more challenging after operations begin, units are in-contact with the threat, and units are out of face-to-face coordination range. Both Childs and Armstrong focused more on just executing information collection rehearsals as opposed to addressing the nature of how to conduct rehearsals after the BCT crosses the line of departure.

Since there is no MTOE BCT collection manager position, units are free to choose who they want, and the results are represented throughout the professional discourse literature. The majority of references to the specific position of the BCT collection manager associate it with a military intelligence lieutenant who often is the information collection platoon leader as evident in nine of eleven training center rotations observed by Adams.[38] This assignment to a lieutenant led to the criticism that the collection manager either does not know ground reconnaissance, experience is limited to

1696 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

technical collection, military intelligence platforms, or is not suited to the demands of the position.[39] Adams' observations from the Joint Readiness Training Center led to a conclusion that "understanding when and how to participate in events, such as the operations synchronization meeting, and incorporating collection tasks into a daily order were often beyond the information CM's level of experience."[40] Gellman recommended the collection manager be filled by a maneuver officer who presumably is best qualified to plan for ground reconnaissance augmented with a subordinate military intelligence officer who brings the technical collection expertise.[41] The other argument for a maneuver leader leading information collection planning is the Chief of Reconnaissance, with an equally diverse recommendation on who should fill that role.

As discussed in chapter 2, Hefti and Palmer offer different recommendations who could fill the non-doctrinal role of Chief of Reconnaissance. Even though the role is non-doctrinal, it is important for the discussion as the arguments center around the fundamental collection management functions defined in chapter one; CRM, COM, and CMM. Hefti's argument for the Cavalry Squadron's Headquarters and Headquarters Troop Commander focuses on the COM functions based on this commander's expectation to understand the BCT's collection platforms and how to integrate ground reconnaissance.[42] Hefti's perspective infers that the Chief of Reconnaissance operates as a cavalry squadron advisor or liaison to the BCT staff on how to employ scouts. As previously stated, Hefti's approach presumes that the Headquarters and Headquarters Troop Commander would be co-located with the BCT planning effort to be effective. Palmer's argument centers around the Squadron Commander fulfilling COM and CMM functions for the BCT collection platforms.[43] Palmer's perspective relies on the Squadron

1697 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Commander's command authority for tasking which would presume that the BCT would task organize the information collection platforms under the Cavalry Squadron. In either construct, the Chief of Reconnaissance fulfills COM functions and therefore is a type of collection manager, just by a different name.

Ultimately which duty position fulfills the role of BCT collection manager is for another discussion. What the literature infers through critique of past experiences in combat training center rotations and observations is the need for a BCT collection manager who can coordinate across the BCT staff and between echelons higher and lower. Further, the importance of this relational coordination cannot be stressed enough since synchronization of platforms requires collaboration with battalion, brigade, and division representatives. The professional discussion appears very clear that a military intelligence leader and a maneuver leader cannot be expected to be subject matter experts in the others platform capabilities. That said, authors did stress the need for expertise in collection platforms and architecture as necessary for successful information collection.

Knowledge in Capabilities and Architecture

The need to understand collection platform capabilities and architecture were represented in eight of the seventeen articles. All eight of these articles directly discussed knowledge in collection platforms as important. Three of the eight articles addressed information collection architecture as well as capabilities. Information collection architecture refers to how information gets from the collector to the person who needs it. Think of information collection architecture as the entire system necessary for information to flow from the sensor to processor to analyst to end user. The literature evaluation resembled a single perspective that BCT collection managers were not

1698 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

knowledgeable of the BCT collection platforms capabilities. Beyond the lack of knowledge, a few articles offered insight on how to close the knowledge in capabilities gap.

Sterioti and Lobdell both discussed the need to understand the request process for platforms where Lobdell mentioned that a significant number of platforms exist above the BCT and outside the Army.[44] LaRubio provides the platoon level perspective by stating that the collection manager needs to know the capabilities and limitations of the RQ-7 Shadow UAS to effectively employ it within the BCT's information collection plan.[45] The failure to understand information collection platform capabilities was discussed in four of the eight articles, several providing observational experience. Adams attributed an observable disconnect between the collection manager, S-2, MICO, and collectors as a failure to understand the capabilities of the platforms.[46]

Buchanan and Covert addressed the gap of knowledge in capabilities and architecture as they discussed an entire training day of the five-day BCT S-2 course was dedicated to "BCT Intelligence and Electronic Warfare Systems and Architecture."[47] The emphasis on organic capabilities followed by a day of employment considerations and collection management training sought to address perceptions of BCT S-2s, as the senior intelligence officers of their formations, unable to integrate their capabilities into the BCT fight. Lobdell, quoting Army Doctrine Publication 2-0, *Intelligence*, discusses how the intelligence architecture requires a knowledge of intelligence capabilities.[48] Adams reiterates the need for understanding intelligence architecture but also stipulates that collection managers must understand maneuver capabilities as a nod to the divergent perspectives between maneuver and intelligence communities.[49] Kuderka and Eickbush

1699 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

placed the blame of failing to utilize organic capabilities on conditioning to the enduring counter-insurgency operations in Iraq and Afghanistan.[50] Kuderka and Eickbush discussed alternative collection platforms such as Air Force Joint Terminal Attack Controllers and other forward observers, although they seem to gloss over the fact that those positions have other primary duties than information collection.[51]

Seven of the total seventeen articles addressed recommendations at closing the knowledge in capabilities gap. These recommendations were wide ranging and encompassed institutional and on-the-job training. Adams correlates units that perform successful information collection are units that also prioritize assigning three to four Soldiers to a collection management team at the BCT which is then capable of covering 24-hour operations.[52] Likewise, Sterioti recommends that an officer or non-commissioned officer be trained as the collection manager prior to any training center or deployment without providing a recommendation on what type of training.[53] Sterioti claims a direct correlation between failures to train collection management in garrison with an ineffective and unsynchronized collection plan.

Although dated, Black and Watras' discussion on the collection management course, precursor to the Q7 Information Collection Planners Course, provides insight in an institutional example of changes made to training to accommodate new requirements. Specifically, Black and Watras mention that following Operation Desert Storm, collection management students would be exposed to new fielded technologies such as UASs and JSTARS as well as integrating between battalion and army component command echelons.[54] Miseli, McLean, and Bovan propose an alternative through sending military intelligence officers to attend the C6 Cavalry Leader Course to better

1700 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

understand cavalry scout planning and integration.[55] This approach to diversifying understanding was credited by Bovan for success in a combat training center rotation.[56] Both the Q7 and C6 additional skill identifiers are discussed in greater detail later in this chapter.

The BCT S-2 course already mentioned earlier serves as another example of training by teaching the leaders of the BCT's intelligence warfighting function. This viewpoint was similarly represented by LaRubio in the form of a capabilities briefing on the RQ-7 Shadow UAS from the subject matter experts to the BCT collection manager.[57] At face value, the thought of a simple capabilities brief may seem elementary, but it belies a deeper inferred point. Understanding that there is no authorized position for a collection manager means that whoever ends up fulfilling the role has another primary job which is likely where that Soldier's attention goes. As Sterioti said "training the collection manager in garrison" is important to successful information collection management. The humble capabilities brief demonstrates that there is a wealth of resources available to the collection manager beyond formal institution training at USAICoE. After all, the AIDP-ISR program demonstrates that a significant resource exists in distance learning through the Defense Intelligence Agency and National Security Agency. Lastly, a collection manager in garrison needs only pick up the phone or walk down to see subject matter experts in the BCT information collection platforms to gain more exposure to the capabilities available.

Support the Commander's Decision Making

Thirteen of the seventeen articles discussed the purpose of information collection was to facilitate the commander's understanding and visualization to enable the

1701 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

commander to make informed decisions. This analysis does not indicate that the remaining articles argue against supporting the commander's decision making, they simply did not mention it. Two viewpoints were represented in the form of a general reminder of the purpose and an attribution of a product and process focused purpose. The general reminder perspective reiterates the importance of the information collection plan in answering priority intelligence requirements and conditions for decision points.

The attribution of a product or process focus is directed at instances where planners put too much emphasis on creating the perfect information collection plan tools, such as the Information Collection Matrix, Information Collection Synchronization Matrix, or Information Collection Overlay, that comes at the expense of detail to the collection platform. Armstrong attributes reconnaissance failure with units that focus on these products, largely dominated by the S-2 section, with no involvement by the S-3 section.[58] Childs stressed the importance of displaying the commander's priority intelligence requirements during the information collection rehearsal to remind participants what the plan is working towards.[59] Adams discusses purpose through accepting that the information collection plan is subject to change and must focus on the commander's priority intelligence requirements.[60]

Adams introduces a concept that is echoed by Palmer and Wellsandt which is the use of mission orders for tasking collection platforms.[61] Both Palmer and Wellsandt use the issue of mission order or task and purpose versus information collection tools as part of the benefit in their proposed organizational changes to place all the BCT collection platforms under the cavalry squadron.[62] In the end, doctrine provides little guidance on how to task collection platforms other than the information collection plan, which

1702 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

remains heavily dominated by S-2 produced tools. The simple answer, offered by Armstrong, puts the responsibility back to the S-3 section in the form of the "staff integrated" written Annex L with the attached appendices provided by the S-2.[63] The results of the literature evaluation analysis is a firm understanding of the overall purpose for information collection and the need for an integrated planning process through trained leaders.

Collection Management Expertise in the BCT

The final contributor to collection management within the BCT is collection management related additional skill identifiers. Specifically, the Cavalry Leader Course graduate, C6, and the Information Collection Planners Course graduate, Q7. According to officer and enlisted tables in the Department of the Army Pamphlet 611-21, *Military Occupational Classification and Structure*, the C6 additional skill identifier provides for a total of eight qualified positions at the Cavalry Troop and Cavalry Squadron Operations cell.[64] Likewise, the Q7 describes the position as "requiring qualifications in managing the employment of organic and supporting intelligence collection assets" but does not include density of positions like the C6.[65] Without providing specifics, the MTOE does reflect a very small number of Q7 positions in the BCT but they are either already factored into an existing staff or unit identified, in table 4, or positioned in a role limiting their ability to doctrinally coordinate the variety of BCT collection platforms.

1703 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 6. Current BCT Collection Management Expertise Analysis

Source: Created by author from data contained in Headquarters, Department of the Army, "Officer and Enlisted Skill Identifiers" in Department of the Army Pamphlet 611-21, *Military Occupational Classification and Structure* (Washington, DC: Government Printing Office, July 2018), accessed 07 March 2019, https://www.milsuite.mil/book/groups/smartbookdapam611-21.

Summary of Analysis

The data clearly shows an increase in information collection platforms at the brigade-level with no primary responsibility for collection management over all of the BCT's information collection platforms. The professional discussions from cavalry and military intelligence leaders provides insight into the value that the collection manager provides through four necessary qualities. Foremost, a collection manager must be an integrator across the staff for effective information collection planning and execution. Secondly, the collection manager must be knowledgeable in organic and external information collection platform capabilities. Third, knowledge in capabilities can create the perfect plan, but understanding the architecture of how the information gets from the sensor to support the fourth quality, the commander's decision making, is key. The

1704 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

collection manager must always focus information collection planning and execution on the commander's priority intelligence requirements to collect timely information for analysts to produce intelligence that facilitate the commander's understanding, visualizing, and decision making. Lastly, a disparity appears to exist in how the maneuver community trains leaders for collection management functions as opposed to how the Army intelligence community approaches it. The cavalry squadron is strongly represented within the BCT for positions coded with advanced collection management training. The BCT intelligence warfighting function is not enabled with advanced collection management training to its detriment.

CHAPTER 5

CONCLUSIONS AND RECOMMENDATIONS

This research sought to determine the value of an authorized BCT collection manager on the MTOE through military intelligence and cavalry doctrine and professional writing. The value of the BCT collection manager was hypothesized as possessing knowledge and skills in collection management processes, information collection tools, and information collection systems. The research and analysis identified recommendations applicable to both senior Army Intelligence leaders and tactical leaders.

Conclusions

This research resulted in four distinct conclusions. First, the growth of information collection platforms at the BCT did not include a corresponding increase in dedicated collection management responsibilities. This increase of platforms and lack of management forces units to treat the collection manager as an additional duty or, less likely, to sacrifice other responsibilities to fill the collection manager responsibilities. It is also a fair conclusion that collection platforms will continue to develop, as stated in the *Army Intelligence 2017-2025* strategic vision, to address gaps identified against peer threats, an example being survivable UAS in a contested airspace environment. Further, it is likely that given growth in capabilities, there is unlikely to be a growth in personnel to accommodate, essentially a do more with the same or less scenario. This would likely require a position for collection management to be taken from an existing role within the staff.

1712 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Second, the professional discussions within the Army maneuver and intelligence communities expands the qualities originally hypothesized for this research. As mentioned earlier, the original hypothesis for this research focused more on the knowledge and skills necessary for a BCT collection manager to integrate the BCT collection platforms through collection management processes and tools. Professionals clearly indicated that knowledge and skills across the process, tools, and systems is important, but does not substitute the need for a leader who can integrate multiple staff representatives and orient on the commander's needs. In essence, the professional discussion encompasses the entire thesis as a single component of a larger discussion of necessary qualities. Therefore, a leader who is capable of working across the staff represents the above center mass quality of capabilities for a successful integrator. In the context of integration, the data reflects that successful integration is less about a single person and more about a team working together to achieve an integrated information collection plan. This expansion of necessary BCT collection manager qualities was unanticipated but clearly reflects the experienced perspectives from the data pool. Relationships matter to integration and represents the quality that most leaders identified as necessary to make information collection management and synchronization successful. The challenge with successful integration then returns to how doctrine defines who is responsible for what within the staff. Doctrine leaves the responsibilities with the staff primaries, such as the S-2 and S-3, without clearly identifying the integrator.

The third conclusion is that doctrine for information collection clearly identifies tasks and requirements for information collection and collection management but does little to fix responsibility beyond the staff primary officer. The professional discussions

1713 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

were fairly clear in identifying that without fixing responsibility, the ownership falls up the chain from the staff primary to the commander. Ultimately concluding that when the commander is deep in information collection management, they are not focusing on other necessary operational requirements. This lack of specificity beyond the staff primary invokes the thought that doctrine is intentionally vague to the point of allowing the commander and staff to determine who best fills the role of an integrator for information collection management. The key point for this conclusion is that professional discussion places a high enough priority on integration that, at the very least, doctrine should clarify responsibility for integration.

The final conclusion determined that advanced collection management training is available for both intelligence and maneuver leaders, but a disparity exists in the distribution of positions associated with this advanced training in the BCT. Table six in chapter four identified that the maneuver warfighting function invests significantly more additional training in leaders at the junior officer and senior non-commissioned officer ranks than the military intelligence warfighting function. How can the intelligence warfighting function contribute through three of the four information collection tasks as defined by FM 2-0, Intelligence; as "collection management, direct information collection, and conduct intelligence-related missions and operations;" without providing dedicated requirements for advanced collection management training?[1] Related to available training, the data demonstrated that opportunities exist in cross training leaders through formal institutional training as well as garrison training.

1714 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Senior Leader Recommendations

There are four recommendations for the Department of the Army G-2, USAICoE Commander, and INSCOM commander in concert with leaders of other centers of excellence. The first is initiate or include a dedicated collection manager position on the BCT MTOE in a force design update. As Sterioti puts it "the Brigade collection manager is the central figure in the collection plan that brings it all together" and Childs expands with "when the collection manager owns the process, develops a simple and logical agenda, compiles the right tools and gathers the right participants together, he sets the brigade up for success."[2] Further, the BCT collection manager position should be coded for at least the Q7, Information Collection Planner additional skill identifier, as well as the C6, Cavalry Leader additional skill identifier. At a minimum, the BCT staff should be authorized one position coded for each of the Q7 and C6 additional skill identifiers. The Department of the Army Pamphlet 611-21 tables for additional skill identifiers should be updated to specify an ideal number of Q7 positions within the BCT, similar to how the C6 additional skill identifier reflects. After all, the Q7, Information Collection Planner Course is the intelligence warfighting functions solution to provide advanced collection management skills. It seems puzzling that there would not be a position on the BCT staff coded for the Q7 considering this research identified a clear increase in the amount and diversity of collection platforms within the BCT.

Implied in the first recommendation is the need to determine which position on the MTOE should be the collection manager. To that requirement, this research recommends additional research to include surveys of BCT S-2s, Division collection managers, BCT S-3s, and BCT Commanders. The additional research should also explore

1715 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

data from the Information Collection Planners course as to the typical training audience and in what capacity they attend. Discussions of who should fulfill the collection manager role typically include the Information Collection Platoon leader, the MICO Commander, a senior all source warrant officer or non-commissioned officer, an assistant BCT S-2, or someone outside the intelligence warfighting function. Considering the scope of responsibility and necessary experience, a senior staff captain in either the intelligence or operations staffs would be a logical candidate to fill the collection manager role. Understanding that every staff position is likely already task saturated, the collection manager role can be reinforced through distributing requirements by the collection management functions of CRM, COM, and CMM.

The second recommendation is for the USAICoE and Maneuver Center of Excellence commands to develop information collection doctrine and organization updates collaboratively. The diversity of information collection platforms identified in chapter four demonstrates that no single warfighting function can own information collection. The appearance of a silo mentality between the maneuver and intelligence warfighting functions on who best plans their respective collection platforms creates unsynchronized collection plans. Since the release of FM 3-0, *Operations*, in 2017 and FM 2-0, *Intelligence*, in 2018, FM 3-55, *Information Collection*, is in need of an update. Updates to FM 3-55, *Information Collection*, should include incorporation of the collection management functions of CRM, COM, and CMM to highlight the integrated staff approach of planning and executing information collection. Additionally, FM 3-55, *Information Collection,* should include a description of the role of the MTOE BCT collection manager.

1716 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The third recommendation is for senior Military Intelligence Corps leaders to update tables 4-3 and 12-2 of Department of the Army Pamphlet 611-21, *Military Occupational Classification and Structure*. The updates to the tables should reflect the coding of BCT positions as collection managers. Further, the tables should reflect a desired objective of at least one Q7 Information Collection Planner on the BCT staff. The tables should also adjust to reduce the restriction to military intelligence branches only and allow maneuver leaders to earn the additional skill identifier.

The fourth recommendation is for the INSCOM commander to expand the Army Intelligence Development Program-Intelligence, Surveillance, and Reconnaissance track to include an abbreviated program of instruction for non-commissioned officers for assignment to BCTs for collection management. This expansion already occurred to accommodate warrant officers. If further research on which position best fits the collection manager results in a warrant officer identified, then the AIDP-ISR could easily expand to accommodate more students.

BCT and Division Leader Recommendations

At the tactical-level, BCT leaders should purposefully assign at least one leader as the BCT collection manager if not a small three to four-member collection management team. Absent of a formally authorized position, the BCT CM's appointment should be as a primary duty to allow them to focus on preparing through training and building relationships across the staff. Prospective collection managers should be leaders capable of working effectively between staff sections and able to lead key processes and events at the BCT-level. BCT leaders must prioritize advanced collection management training of either the Q7 Information Collection Planner or C6 Cavalry Leader for any leader filling

1717 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

collection management functions. A staff captain in the S-2 section is a logical starting point for consideration as the collection manager. The S-2 captain likely has the requisite knowledge of information collection platforms, at least the military intelligence systems, as well as basic institutional training in information collection planning tools. The S-2 captain may be better able to integrate with other staff sections for collaborative planning. This recommendation certainly acknowledges that there is not a plethora of extra staff members to easily assign the collection manager role without the risk of losing focus in other requirements. The data reflects how important the collection manager is to enable effective decision making.

BCT S-2s, Division collection managers, and G-2s should develop training plans for subordinate collection managers that includes capabilities, limitations, and employment considerations of information collection platforms at every echelon. collection manager training should also include thorough instruction in mission command system architecture. collection managers should understand how information is moved from collection platform to analyst to the commander. The information collection planning and execution effort should be trained and planned just as the analytical effort within the unit training plan. These training plans should include capabilities briefs, site visits, leader professional development sessions, web-based training, institutional training, and practical exercise application in a field environment.

Lastly, BCT S-2s should build standing operating procedures and counseling within the intelligence staff and influence the entire BCT staff with identifying the collection management functions of CRM, COM, and CMM. By incorporating these collection management functions, the staff may be able to better integrate through better

1718 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

understanding of distributed responsibilities. An example would be specifying that the BCT S-2 operations officer in the command post fulfills COM functions by monitoring and providing awareness to the staff of what collection platforms are active and where they are collecting. Likewise, this position could also be identified to maintain the current information collection matrix to facilitate COM should a tasked collection platform become unavailable and require re-tasking of a different platform. Each staff section could also identify a position to serve as their respective CRM to facilitate the consolidation of generated information requirements.

Ultimately these recommendations represent practical actions that senior leaders and tactical leaders can take to improve information collection within the Army and their formations. The operational environment is only growing more complicated, the architecture to support information movement is growing more complex, and the capabilities to gather the information is increasing. The goal of delivering "intelligence at the speed of mission command" is only achievable effectively if the collected information gets to an analyst to produce intelligence to support the commander's decision making. To do that, information collection must be managed and integrated through a dedicated team effort at the BCT.

13. ABSTRACT (maximum 200 words)

This capstone project studied the mission utility of using unmanned aerial vehicle (UAV) systems to accomplish the over-the-horizon mission by modeling a variety of UAV capabilities and evaluating their contribution. An Excel probabilistic model of the mission was created to determine the optimized weapon loadout and swarm configuration, which assumed the electronic countermeasures (ECM) UAV to have the highest probability of enemy engagement due to its lead formation position and large radar signature. An ExtendSim simulation added a time element to the study. Both the model and simulation revealed that a maximum air-to-air and strike weapon loadout, which is four weapons for each role, yields the highest probability of success at the lowest probability of a UAV casualty. A maximum air-to-air and strike loadout was found to produce success and UAV casualty probabilities of 98 and 3 percent, respectively. A comparative cost analysis assessed the financial viability of substituting UAVs for manned platforms. The analysis found the unit and per-flight hour cost, for all UAV platforms except those that fulfill the ECM role, to be less than the cost for manned counterparts. However, the use of the ECM UAV eliminates the potential for a flight crewmember casualty.

EXECUTIVE SUMMARY

Naval Air Warfare Center, Weapons Division, China Lake, is developing an automated decision aid for over-the-horizon targeting (OTH-T) and strikes (OTH-S), called the Battle Readiness Engagement Management (BREM) system. The BREM system, which is currently in the research and development phase, is envisioned as a decision aid to military decision makers by evaluating different OTH courses of action based on game theory and artificial intelligence. The BREM project has developed a prototype OTH targeting and strike game for evaluating a wide range of challenges, actions, and outcomes based on complex "real world" conflicts.

The BREM game's initial scope includes air-launched OTH smart weapons and similar adversarial threats. The primary area of interest of this project is to expand the BREM scope to include the utilization of unmanned aerial vehicles (UAVs). The unmanned platform has the potential to redefine the battlespace by augmenting many existing capabilities, such as carrying offensive missile payloads and electronic warfare pods, as well as providing OTH sensor surveillance and defensive capabilities. Operating multiple UAVs in a swarm allows for a mix of UAVs with specialized payloads, to further shape the battlespace.

Research began with developing a concept of operations (CONOPS). The CONOPS consists of the baselined interactions, strategies, and configurations for how a system of UAV systems can provide capabilities for OTH missions. With the incorporation BREM, the goal is to achieve the highest chance of mission success while using the fewest amount of resources. To do so, inputs such as the operation scenario, available resources, and threat data feed into a decision matrix. At this point, the decision matrix serves as the brains of the system, autonomously generating an optimized plan of attack. This plan will consist of the number of UAVs required for the mission, which type will be most effective, loadout configurations for each unit, and the strategy for executing the mission.

Establishing this functionality served as a launching point for architectural analysis. The DOD Architecture Framework (DoDAF) 2.02 was utilized as a guideline for capturing

1741 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the overall architecture. The UGN team was able to capture and illustrate many factors of the OTH mission: physical assets, the interaction of external systems, the flow of functionality, internal systems, internal communications, and functional allocation. The in-depth knowledge acquired from these DoDAF models fueled the development of modeling and simulation parameters.

The goal of the modeling and simulation effort was to quantify the effectiveness of various factors of an OTH strike mission. Modeling focused on two critical probabilities: the probability of striking the OTH target and the probability of a swarm UAV being hit. Both are driven by factors such as UAV selection, UAV performance, and enemy proficiency. Simulation enabled the UGN team to reinforce the data collected with modeling. The same performance parameters were used, but simulation provided a better representation of a live combat scenario (i.e., not targeting downed targets). Through modeling and simulation, the strike UAV was found to be the critical UAV platform for the successful engagement of the OTH target. In addition, loss of the strike UAV had the most detrimental impact on the success probability of the OTH strike mission.

This UGN team is convinced the results of the modeling and simulation effort can aid in developing further analyses to unlock new capabilities to be implemented in the OTH mission. An Excel application and ExtendSim model will be the near-term deliverables provided to support BREM development. This data provides a sufficient baseline, but the UGN Team recommends the swarm size analysis be repeated using real-world probabilities for UAV effectiveness and reliability.

I. INTRODUCTION

The over-the-horizon (OTH) mission is one of the most challenging engagements for modern weapons systems. The mission engagement is driven by the complexity of data transfer of target information due to the break in the line of sight from the horizon, as well as sensor error budgets from long mission execution times. The mission is further strained by the limits of weapons loadouts and adversarial counter-tactics. The complexities of the OTH mission area present a decision space that can benefit from automated decision aids to support human warfighting decision makers. Automated decision aids could support the selection of sensors for target data support and the selection of available weapons.

The Naval Air Warfare Center, Weapons Division, China Lake, is developing an automated decision aid for OTH missions, called the Battle Readiness Engagement Management (BREM) system (Nagy 2019). The BREM system, which is currently in the research and development phase, is envisioned as a decision aid to military decision makers by developing and evaluating different OTH courses of action. The BREM system incorporates game theory and machine learning to develop OTH courses of action and evaluate these options based on expected consequences and predicted adversarial responses (Johnson 2019). The BREM system will develop battle plans to determine when and how to use kinetic and non-kinetic weapons to support various OTH targeting and strike missions. The BREM program is using an incremental learning approach to ensure readiness in the successful execution and management of missions involving complex planning. This learning approach includes de-escalation tactics while also recommending the selection of available weapons, communications, and sensors that yield the highest likelihood of mission success. The BREM system is focused on leveraging the increased readiness provided by the system to reduce casualties and maximize results.

The BREM system's initial scope includes air-launched smart OTH weapons and similar adversarial threats. One area of interest is an expansion of the BREM system to include the contribution of unmanned aerial vehicles (UAVs) to the OTH mission. This capstone project studied the mission utility of adding UAVs to the OTH mission by modeling a variety of UAV capabilities in conjunction with the BREM system. The study

1743 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

looked at the use of different types of UAVs (missile payload, electronic countermeasure [ECM] pod, sensor, defensive, etc.) in different configurations and combinations (single UAVs to swarms of UAVs) using modeling and simulation to evaluate probabilities of mission success. The study supports the incorporation of UAVs as contributors to OTH mission operations into the BREM system decision space.

A recent NPS systems engineering student team developed an operational scenario and conceptual design architecture for the BREM system with a focus on weapons selection and determining salvo size and weapons trajectories (Fava et al. 2019). The student team compared the use of a future BREM system in an operational scenario to a purely human decision process. This showed how a BREM system may be incorporated into future OTH missions and how the automated decision-making capability could be leveraged across platforms to enable autonomous OTH multi-mission engagement.

This capstone project built upon the foundation laid by the previous NPS systems engineering student study (Fava et al. 2019) to model and analyze the contribution of UAVs to the OTH mission domain. The goal of this project is to provide an understanding of the operational utility of adding UAV capabilities to OTH missions. In addition, this capstone project aims to support the implementation of the UAV OTH decision space within the BREM gaming system. The capstone project team has conducted a systems engineering modeling and simulation analysis to capture the functions, architecture, data flow, event sequences, and concepts of operation used in various combinations and configurations of UAVs to assess the factors involved in improving OTH missions.

A. PROBLEM STATEMENT

The OTH mission presents a complex and stressing military decision domain for tactical decision makers. The complexity of this mission arises from incomplete and often inaccurate knowledge of the battlespace; the speed, kinematics, autonomy and destructive capabilities of modern strike weapons; unknown aspects of the adversary; unpredictable consequences of tactical decisions; adversarial means of obfuscation, countermeasures, and counterstrikes; and the general complexities of the operational environment including the beyond-line-of-sight distances. The complexities of the OTH mission area present a

1744 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

decision space that can benefit from automated decision aids to support human warfighting decision makers. The Navy is developing the BREM system as an automated OTH decision aid; however, BREM is not complete and currently lacks the consideration of naval UAV assets as contributors to the OTH mission space. This capstone study addresses this need by analyzing the potential contributions of UAVs to the OTH mission and supporting the implementation of adding this knowledge to the BREM decision aid system.

B. CAPSTONE PROJECT OBJECTIVES

The primary objective of this capstone project was to study the mission utility of adding UAVs to the OTH mission by modeling a variety of UAV capabilities in conjunction with the BREM game system. The study looked at the use of different types of UAVs (such as those with payload, ECM, sensor, and air-to-air defensive capabilities) in various configurations and combinations (single UAVs to swarms of UAVs) using modeling and simulation to evaluate probabilities of mission success. An additional objective of the study was to support the incorporation of UAVs into the BREM mission planning game system.

C. SCOPE, ASSUMPTIONS, AND CONSTRAINTS

The focus of this project was the application of a systems engineering analysis process to study the potential contribution of UAV capabilities for the OTH mission. Therefore, the scope of the project included:

- naval UAV assets
- OTH targeting and strike missions
- BREM as a decision aid under development
- modeling and simulation methods of performance assessments

The assumptions and constraints for this project were generated based upon the need for defining some of the mission parameter unknowns. These assumptions were used

1745 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

to reduce the complexity and bound mission parameters for the probabilistic analysis of systems performance. The assumptions are as follows:

- The OTH mission is not dependent on a single surface ship type for the OTH swarm mission execution
- OTH targets have a maximum return fire capability of four rounds.
- The performance of the return fire threats will be susceptible to electronic countermeasures ECM.
- The target tracking of the return fire threats is radar-based.
- The minimum UAV selection for the swarm engagement includes at least one strike UAV.

D. METHODOLOGY

The team developed a tailored system engineering analysis approach, as shown in Figure 1. As with a traditional "Vee" systems engineering process, definition and decomposition occurred as the project traversed down the left side, and testing and integration occurred as the project continued up the right side. This approach began with concept development, which included the development of a concept of operation (CONOPS). The CONOPS was then used to transition into the architectural analysis and the development of functional and architectural models based on the Department of Defense Architecture Framework (DoDAF). After completing the functional/architectural analysis, these models were used to create parameters for a mission execution simulation. After simulation development, the team evaluated the model evaluation and studied the analysis results.

1746 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

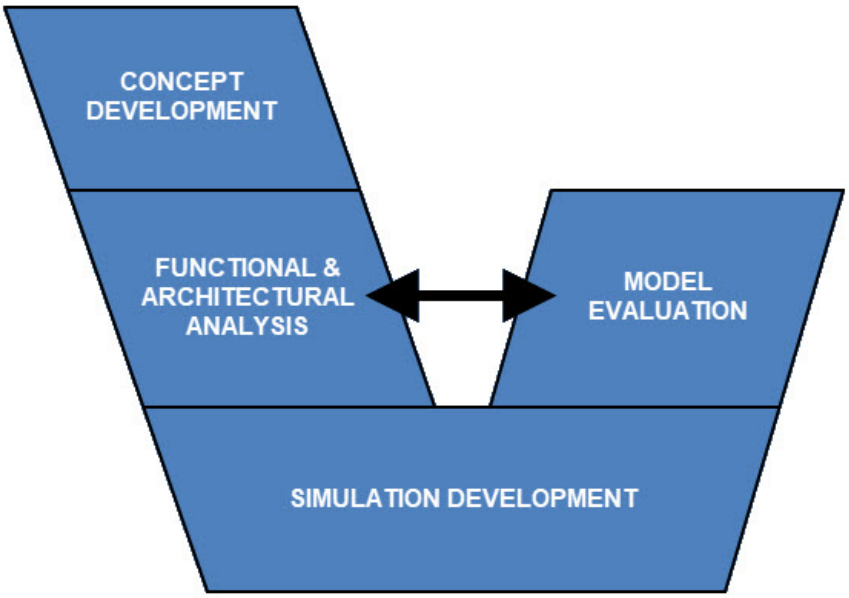

Figure 1. Modified Systems "V"

E. TEAM ORGANIZATION

Each team member had an identified set of roles and responsibilities that enabled the successful completion of the project. The fulfilled responsibilities are identified as follows:

Team Lead—Rod Harris

- Responsibilities: setup meeting agendas, kept meetings on track, kept workload distributed, kept team members accountable for attendance and deliverables

Lead Editor—Joshua Taylor

- Responsibilities: reviewed and submitted all deliverables, supported tracking, review, and accountability of deliverables

Systems Development Lead—Chris Kleparek

- Responsibilities: Ensured the systems engineering processes were being utilized, posted meeting minutes and actions to the Sakai team resource site, tracked-and-closed actions

1747 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Modeling and Simulation Lead—Chadwick Boyd

- Responsibilities: strategically organized architecture, modeling, and simulation solutions to ensure project objectives were achieved

Specialists, Analysts—All

- Responsibilities: remained accountable and diligent for completing tasking

F. CAPSTONE REPORT ORGANIZATION

The purpose of this report is to capture the analysis and results of the project execution. The report follows the systems engineering approach previously described. Chapter II presents the team's OTH UAV concept of operations (CONOPS). Chapter III contains the team's architectural analysis that describes the OTH UAV system of systems and functional architecture. Chapter IV describes the team's modeling and simulation analysis and performance analysis results. Chapter V reflects on the report's findings, identifies contributions, highlights potential benefits, and outlines future work to be undertaken by successive efforts.

Reflecting on Chapter I, the problem and scope of the project was defined and the underlying assumptions and constraints were identified to aid the reader in realizing the goal for this project. In addition, the team organization, project methodology, and report organization were introduced to provide the reader with a better understanding of the team element undertaking this project. Moving into Chapter II, the CONOPS, types of UAVs, operational scenarios, and battle strategies will be discussed to provide the foundation for the modeling and simulation effort.

1748 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

II. CONCEPT OF OPERATIONS FOR UNMANNED AERIAL VEHICLES TO SUPPORT OVER-THE-HORIZON MISSIONS

The team developed a concept of operations (CONOPS) as a basis for developing a model and simulation (M&S) of UAV operations to support the OTH mission. The CONOPS details the operation of UAV systems of systems (SoS) in conjunction with the BREM decision aid system during an over-the-horizon targeting (OTH-T) and strike (OTH-S) mission. The CONOPS consists of the baselined interactions, strategies, and configurations for how a UAV SoS can provide capabilities for OTH missions. Establishing a CONOPS serves as a launching point for more in-depth content of the project: it provides the information necessary to develop architectural DoDAF models (Chapter III) and serves as the basis for parameter selection and M&S development (Chapter IV and V).

A. CONCEPT OF OPERATIONS DESCRIPTION

This CONOPS provides details of how UAVs could operate in conjunction with BREM decision aid system to improve OTH missions. Figure 2 illustrates this operational concept. Adding blue force UAVs as a SoS to the OTH mission can improve situational awareness, threat targeting, communication, countermeasures, and both defensive and offensive OTH actions. The role of the BREM system, as a decision aid, is to determine how a UAV SoS can best support the gathering of threat data and battle strategies (such as formations, loadout selection, resource management) to improve OTH missions. This CONOPS focuses on the successful utilization of blue force assets to neutralize a present threat, whether engaged in an offensive or defensive combat scenario.

1749 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

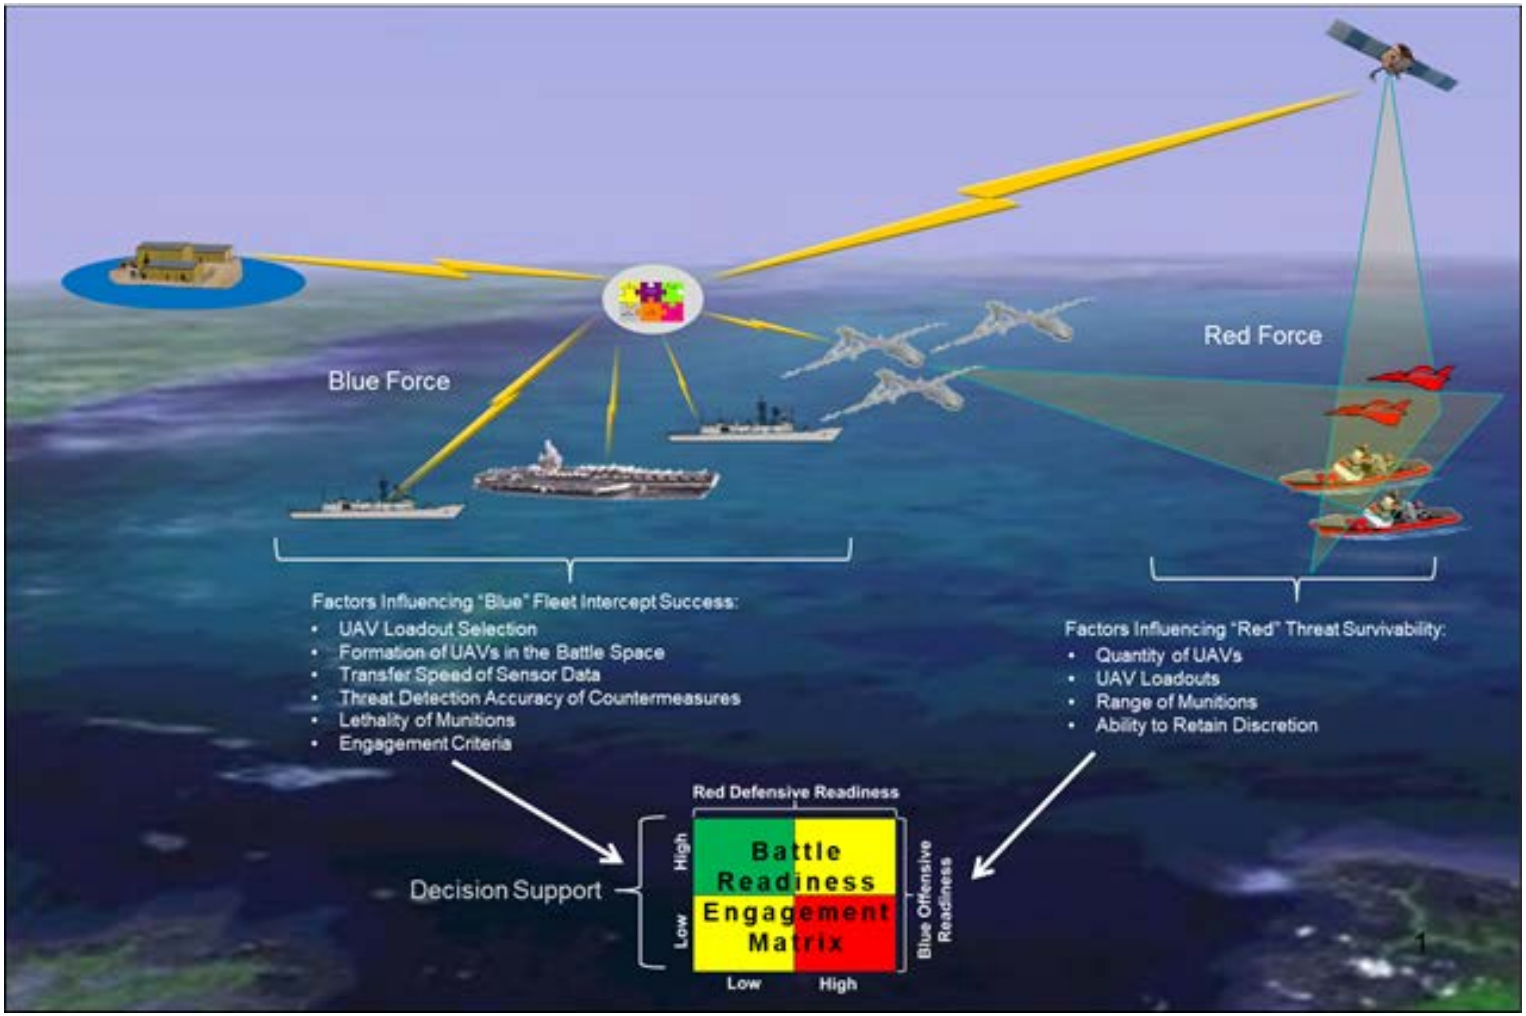

Figure 2. OV-1: Operational Concept for BREM and UAV SoS for OTH Missions

1750 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The CONOPS details the structure of the UAV system of systems (SoS) and its relationship to the BREM system. The CONOPS is based on information that is leveraged from Department of Defense weapon system experience and research detailing stochastic game theory, battle simulations, capabilities-based planning, and systems development. The CONOPS considers current capabilities for UAVs, radar, communications, and weapon systems.

As illustrated in Figure 2, the OTH mission domain includes blue force assets such as a naval strike group that can perform strike missions against a red force. The red force may defend itself with countermeasures and warfare strikes such as missile launches from ships and aircraft. The BREM system is shown in the figure as a colored cube representing this decision aid system that develops OTH courses of action (COA) and also evaluates the risk level of each COA—as green, yellow, or red. This CONOPS describes the use of the BREM system to determine how a UAV SoS could best support the blue force's OTH mission. The BREM tool would be used to deliver an estimation of the probability of success of COAs involving the engagement conditions of a given scenario. The engagement conditions include the following: types and quantity of blue force UAVs present, types and quantity of red force UAVs present, radar detection rates, ECM success rates, missile neutralization rates, and missile intercept rates.

The BREM is a tool used to illustrate this desired readiness condition. Mission success, represented as a green condition, is achievable through the informed use of available resources. Suggestions regarding resource allocation will aid decision makers in determining the actions required to maximize the probability of mission success while minimizing friendly casualties. Figure 3 depicts a high-level flow chart of BREM functionality. The system will take the mission scenario, analyze current resources and threat data (such as quantity, weaponry, vulnerabilities), and generate an optimal plan of attack. This plan will consist of the number of UAVs required for the mission, which type will be most effective, loadout configurations for each unit, and the strategy for executing the mission. This strategy will consist of communication, UAV coordination, reporting of sensor data, firing of weaponry, deployment of countermeasures, and all other functions required for mission success.

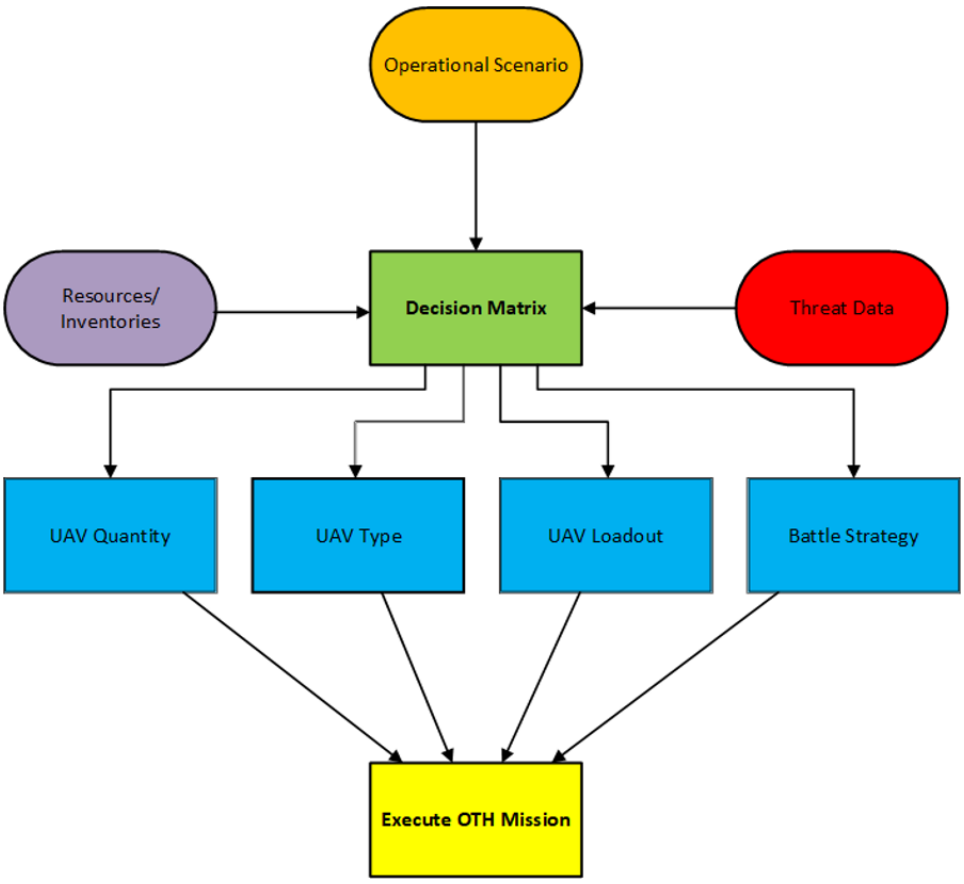

Figure 3. Operational Flow Chart

B. TYPES OF UNMANNED AERIAL VEHICLES

1. Sensor-Enabled Unmanned Aerial Vehicles

Sensor-enabled UAVs support the target and threat detection and tracking data needs for the blue force. This type of UAV supports the OTH-T mission. This information may then be used to support UAVs capable of electronic countermeasures (ECM), air-to-air (A/A) strikes, or air to ground target strikes. The sensor-enabled UAVs improve target and threat data fidelity and provide data used for battle state assessments.

2. Air-to-Air Defense Unmanned Aerial Vehicles

Equipped with antiballistic missiles, A/A defense UAVs are capable of countering incoming missiles. These UAVs are responsible for the completion of the inbound missile

1752 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

target OTH-S missions. The capability to combat incoming threats reduces the probability of damage to a UAV in the swarm and increases the likelihood of mission success.

3. Strike Unmanned Aerial Vehicles

Strike enabled UAVs are capable of engaging and neutralizing enemy targets. These UAVs support the offensive attack portion of the OTH mission. This type of UAV's probability of kill success contributes directly to the overall OTH mission success.

4. Electronic Countermeasures Unmanned Aerial Vehicles

UAVs equipped with ECM are capable of jamming the electronics of enemy threats, thereby reducing the red force's probability of successful attacks against the blue force. ECM UAVs target the red force's radar homing systems. Effective use of ECM UAVs will reduce the likelihood of damage to the blue forces and will increase the blue force's probability of OTH mission success.

C. OPERATIONAL SCENARIOS

1. Unmanned Aerial Vehicle Strike Mission

The OTH strike mission occurs when an OTH target is identified. During this event, the user-supplied target location and identification will be used by the BREM decision aid system to assess the number of assets to deploy to meet and predicted probability of success. In the event that a strike UAV is selected to support this mission, the strike UAV must acquire, track and engage the target. The engagement will be consummated with a missile deployment. Mission success will depend on the strike UAV probability of survival as well as the probability of a successful missile intercept by the red force.

2. Unmanned Aerial Vehicle Sensor Mission

The surveillance mission requires a percentage of radar coverage for a specified area based upon the user inputs. User-supplied radar capabilities are used by the BREM decision support system to generate the number of sensor-enabled UAVs required to maintain the desired domain coverage. The sensor-enabled UAV mission success will be dependent on the radar quality of sensor-enabled UAVs in support of the OTH target

1753 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

acquisition and track. The OTH target track data is sent to the OTH strike UAV to improve its probability of missile intercept success.

3. Unmanned Aerial Vehicle Missile Intercept Mission

The OTH missile intercept mission requires allocation of an intercept missile loadout based on the user assessment of the OTH target's return fire salvo size. This mission occurs during an inbound missile threat. During this event, the A/A UAVs must launch missiles to intercept the enemy missile. Significant factors influencing the success of this type of mission is the number of inbound missiles, the number of A/A UAVs, the velocity of an inbound missile, distance from an inbound missile, detection distance, target acquisition time, missile inventory, and missile intercept rate. The mission success will be assessed as a probability of intercepting inbound missiles.

4. Unmanned Aerial Vehicle Electronic Countermeasure Mission

The ECM mission requires a specific jamming energy output based on user input regarding the OTH target's return fire capability. The jamming performance factors include distance and angle to incoming threats, as well as, the ECM UAV position in relation to the target of the inbound threat. The ECM UAV mission success improves the UAV survivability by decrementing the intercept performance of inbound threat missiles.

5. Over-the-Horizon Unmanned Aerial Vehicle Target Mission

The OTH UAV target mission occurs when there is in inbound non-weaponized UAV threat. An example of this type of mission would be an enemy UAV equipped with cameras dedicated to retrieving intelligence. During this type of mission, strike UAVs must be employed to neutralize the enemy threat. Major factors influencing the success of this type of mission are the number of strike UAVs, enemy UAV velocity, missile kill-rate, missile inventory, missile velocity, and distance from an inbound missile.

6. Over-the-Horizon Unmanned Aerial Vehicle Swarm Mission

The UAV swarm mission relies on the efforts of each type of UAV in the SoS: sensor-enabled, air-to-air, strike, and ECM. The swarm mission simulates two opposing

1754 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

swarms of UAVs, and mission success is defined by the complete neutralization of the enemy UAVs. During this mission, blue force UAVs must defend their team from inbound missiles and attack the opposing force. This mission is composed of independent OTH Missile Intercept Missions and OTH UAV Target Missions. In addition, ECM UAVs are employed to help defend the blue force by reducing the blue force casualty rate during the engagement with the red force.

7. Communications

a. Ship-to-Ship Communications

The firing ship can receive data from support ships that include incoming threat data. The threat data covers the target states, such as position (altitude and range), velocity, and target type (such as maneuvering or sea skimming). The firing ship can also send and receive data about BREM states. The BREM data will be used to support weapons selection decisions.

b. Sensor-Enabled Unmanned Aerial Vehicle-to-Ship Communications

The firing ship can receive data from support sensors that include incoming threat data. The threat data covers the target states, such as position (altitude and range), velocity, and target type (such as maneuvering or sea skimming). Sensors will also communicate environmental data for mission support.

c. Ship-to-Unmanned Aerial Vehicle Communications

The firing ship can send data to the UAVs that include incoming threat data. The threat data covers the target states such as position (altitude and range), velocity, and target type (such as maneuvering or sea-skimming) as well as environmental data such as the presence of radar jamming.

d. Unmanned Aerial Vehicle-to-Ship Communications

The UAV released for intercept engagement will communicate the status of target acquisition, target tracking, and target kill to the firing ship.

1755 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

e. UAV-to-UAV Communications

In a swarm UAV engagement, the UAVs will communicate the status of target acquisition and target track to the other UAVs. The UAVs may also transmit threat data required for target tracking.

D. MISSION BREAKDOWN

The BREM OTH scenario is a battle group mission. It includes the identification and tracking of an incoming threat or OTH target as well as the identification of the likely target. The nominal scenario starts with sensor support systems, shipboard or external, picking up a likely threat or OTH target. The threat/target information is delivered to the battle group, where the threat/target is identified as the OTH target. At this point, a target track is established using the available sensor. The sensors may be down-selected based on expected intercept complexity. The down select option allows the sensor resource to be reallocated to other tasks or shut down to prevent overuse. Once the track/position is established, target data is sent to the battle group. Based on the target data, the firing ship is selected from within the battle group. The firing ship then determines which UAV or UAV group to use for the intercept engagement. After UAVs are released, the continuation of UAV support with target state data is determined and supported if needed. The sensor systems continue to track the engagement. If the intercept/OTH mission fails, the scenario iterates until the threat is neutralized.

E. BATTLE STRATEGIES

Once the threat has been identified using a ship's radar sensing system, the BREM program selects the optimal ship to launch the unique UAV or UAV swarm with the highest probability of destroying the target. Unique UAVs are on board each vessel with different weapon selections, flight characteristics, and missile inventory. It is up to the BREM program to leverage the ship's position with the UAV information to defend against or attack the enemy. This program must also consider swarm engagement approaches and future engagements in the battle theater space. Table 1 lists types of BREM input and output, and scenario manager functions.

1756 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 1. BREM Input, Output, and Scenario Manager Functions

Input	Ship positioning (coordinates in the battle theater)
	UAV loadout (quantity for each variety on each ship, UAV weapon inventory)
	Remaining missions (number of probable future engagements
	Ship sensor data (number of threats, threat positions)
	UAV sensor data (number of threats, threat positions)
	Target (threat ID, trajectory, speed)
Output	UAV selection (ship selection, UAV team selection, weapon usages, lethality determination)
	Engagement decision (single UAV vs multiple, engagement success rate)
Scenario Manager Functions	User may select alternative UAVs to engage or create a new class of UAV
	Evaluate new engagement success rate under new theater space criteria

The engagement decision system utilizes three sets of decision factors (surface ship and UAV selection factors, event decision factors, and target decision factors) to develop the optimal battle strategy output.

Surface Ship and Unmanned Aerial Vehicle Selection Decision Factors

The position represents the coordinates of the ship in the battle theater. Each ship in the battle theater can launch its own set of UAVs teams at approaching threats and targets. The UAV loadout to be launched depends on the UAVs remaining on each ship. The multiple loadout values represent the remaining UAVs (of varying capabilities) available to execute battle tasks such as payload delivery, missile attacks, EW, and surveillance. The ship's UAV reserves are critical to ship and UAV selection. The remaining missions is another variable that is unique to each vessel.

The remaining missions are the expected number of future mission engagements based on the total number of missions allocated minus the number of missions executed. If

1757 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

a ship is likely to engage at least three more times in the theater space, there must be the appropriate resource allocation for each engagement. The resource allocation must account for missiles, UAVs, and UAV capabilities. The BREM program may require events such as payload drop-offs and ship-to-ship UAV transfers to maintain the optimal readiness condition. The fourth and final variable that is unique to each ship is the available sensor data. This sensor data is used to detect incoming threats and enemy UAVs. Due to each ship's unique positioning, each will encounter differing battle events.

1. Event Decision Factors

The target threat level represents the likelihood (*p)* of the threat to cause damage. This factor will be used in the UAV selection decision, and more specifically, the UAV quantity decision. Although the user of the BREM program may manipulate the target threat level, the default value will be set at 0.5. By increasing the threat level, the optimal position in the BREM will require a more significant swarm or attack force to neutralize the target. By decreasing the value below 0.5, non-violent approaches are preferred to reduce the likelihood of future casualties.

2. Target Decision Factors

Before selecting the appropriate means of engagement, the target attributes need to be identified and processed. Factors such as the position, trajectory, speed, and maneuverability of the target will be used to determine the optimal means of neutralization, counterattack, or surveillance approach. The ship and UAV selection are heavily dependent upon these factors. If an inbound threat is approaching a ship containing a UAV team or a non-weaponized UAV, the ship selection becomes critical to incepting the inbound threat. In this type of scenario, if a nearby UAV is in flight, it will be considered to intercept new threats.

Reflecting on Chapter II, the CONOPS, types of UAVS, operational scenarios, and battle strategies were discussed to provide the foundation for the modeling and simulation effort. Moving into Chapter III, the operational and system architecture will be defined to illustrate the relationships required between the swarm assets for mission execution.

1758 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

III. ARCHITECTURAL ANALYSIS OF A SYSTEM OF UNMANNED AERIAL VEHICLE SYSTEMS IN SUPPORT OF THE OVER-THE-HORIZON MISSION

The capstone team performed an architectural analysis of the UAV SoS for the OTH mission. The team developed architectural views based on the Department of Defense Architectural Framework (DoDAF) to capture both operational and system views of the UAV SoS. This analysis was performed to aid in the refinement and maturation of the CONOPS, to inform the UAV SoS swarm size performance analysis, and support the UAV modeling and simulation.

A. DEVELOPMENT OF BREM SYSTEM ARCHITECTURE

The architectural analysis for the OTH mission focused on describing the UAV SoS functions and architecture. The analysis generated a system architecture for the proposed OTH mission using model-based system engineering (MBSE) tools. The identification of internal and external system interactions resulting from the architectural analysis supports the future BREM system as well as the team's M&S analysis.

With the understanding of how the system is expected to operate, who is involved, and what are the assumptions and parameters of the system as developed in the CONOPS, the architecture analysis took a top-MBSE approach. This approach utilized the DODAF 2.02 as a guideline for capturing the overall architecture. The team selected Innoslate's model-based systems engineering software Innoslate to develop the DoDAF viewpoints. Knowledge of the system and parameters generated were input into Innoslate, which was then used to generate various views of the system to show operational and system-level interactions.

Utilization of the Innoslate tool offered various ways to depict the interaction of systems and subsystems, both internal and external, involved in the execution of the OTH mission. The DODAF was used to model the core functions of the BREM system as well as the various interactions between internal and external systems required for swarm operation. The overarching DODAF views focused on for this architecture of the system

1759 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

were the operational and systems viewpoints. We chose these viewpoints to illustrate the system-to-system operation as well as the execution and exchange of information between assets. When examining the views, we recommend approaching them from the perspective of an external, high-level user as many of the finer system-related details have yet to be considered.

The following are specific viewpoints developed and brief reasoning for selection:

- OV-1: High-Level Operational Concept Graphic—Offers the high-level graphical depiction of the system's operational concept
- OV-5a Physical Context Hierarchy—Captures the physical assets of the OTH mission
- External Systems Diagram (IDEF0)—Captures the functional decomposition of the mission environment and the interaction between external systems required for the execution of the BREM swarm mission.
- OV-5b: Operational Activity Model and sub-assembly decompositions—Defines the relationship between the external systems and the OTH mission as well as the internal relationships captured in the IDEF0 format
- OV-6c: Event Trace Description—Captures the sequence of events required for the OTH mission
- SV-1: Systems Interface Description—Identifies the internal systems associated with the OTH mission
- SV-2: Communications Network Diagram—Captures the intra-swarm communications required for the execution of the OTH mission
- SV-4a Functional Hierarchy—Captures the functional allocations for the OTH mission

The knowledge gained during the development of the diagrams that support the system architecture and design will aid the modeling and simulation development.

1760 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

B. OPERATIONAL ARCHITECTURE

The operational architecture view (OV) describes the operations of the system and the connections among the system and subsystems. The OV allows for evaluation of operational requirements, evaluation of interoperability issues, and system baseline. The decision was made to focus on the system analysis through the development of an OV-1, OV-5a Physical Context Diagram, OV-5b F1 External System Diagram and F2/F3 Sub-Functions decompositions, and the OV-6c Event Trace Diagram. These operational viewpoints are described in Table 2.

Table 2. DoDAF Operational Architecture for OTH Mission

DoDAF Operational Viewpoints Developed for the OTH UAV SoS	
OV-1: High-Level Operational Concept Graphic	Offers the high-level graphical depiction of the system's operational concept (Note—this is located in Chapter II of this report)
OV-5a Physical Context Hierarchy	Captures the physical assets of the OTH mission
External Systems Diagram (IDEF0)	Captures the functional decomposition of the mission environment and the interaction between external systems required for the execution of the BREM swarm mission
OV-5b: Operational Activity Model and sub-assembly decompositions	Defines the relationship between the external systems and the OTH mission as well as the internal relationships captured in the IDEF0 format
OV-6c: Event Trace Description	Captures the flow of the functions performed by each UAV during the mission execution

1. OV-5a: Hierarchy Diagram—Physical Context Diagram

The hierarchy diagram outlines the decomposition of the physical assets allocated to the BREM swarm mission execution. The physical hierarchy includes the system decompositions, as shown in Figure 4. The battle group contains the UAV swarm that will be responsible for mission execution. The UAV decompositions capture the asset's specific needs for each of the UAV configurations. The analysis used to develop this diagram reinforced that the system's assets are captured and allocated to operational activities, which are represented in the system's architecture views (SV).

1761 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

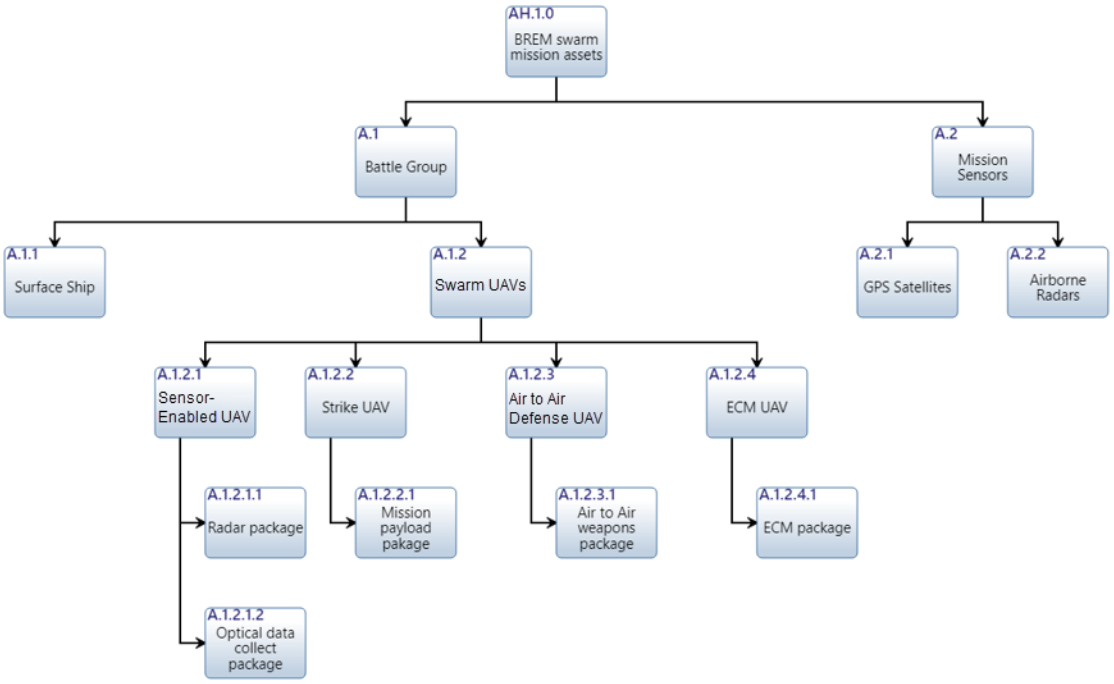

Figure 4. OV-5a: Physical Context Hierarchy

2. OV-5b: Operational Activity Diagrams

The operational activities models describe the interactions and relationships of the various system required to execute the OTH mission. These diagrams, shown in Figures 5 through 10, establish the functional architecture and identify the interactions between swarm assets and external conditions. As the team developed the architecture, each of the functional decomposition levels where labeled. The Level F-1 External System Diagram is the top of the systems architecture, the Level F-2 Execute Mission Diagram is a decomposition of the execute OTH mission function from the F-1 diagram, and Level F-3 Sub-Function decompositions of the OTH mission are captured in the remaining diagrams.

3. Level F-1 External System Diagram IDEF0

The External System Diagram (Level F-1) depicts the functions of the external systems as an SoS architecture. It also illustrates the data flow between each of the external systems. External systems include the OTH mission support systems that will not be decomposed as part of the swarm UAV architecture. The diagram aids in understanding

1762 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the cooperative nature of the external systems and the architecture of the SoS utilized in the OTH mission execution.

The external systems captured in the external systems diagram include GPS satellites, airborne tracking radars, and surface ships. These systems provide functions such as; GPS target tracking, radar target tracking, mission parameters, and launching the swarm UAVs. These functions are required for the execution of the mission but cannot be accomplished by the swarm UAVs. In this architecture, the swarm UAVs are responsible for the execution of the OTH mission functions. These functions will be decomposed in the throughout architecture. The operational relationships for these systems are shown in Figure 5.

1763 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

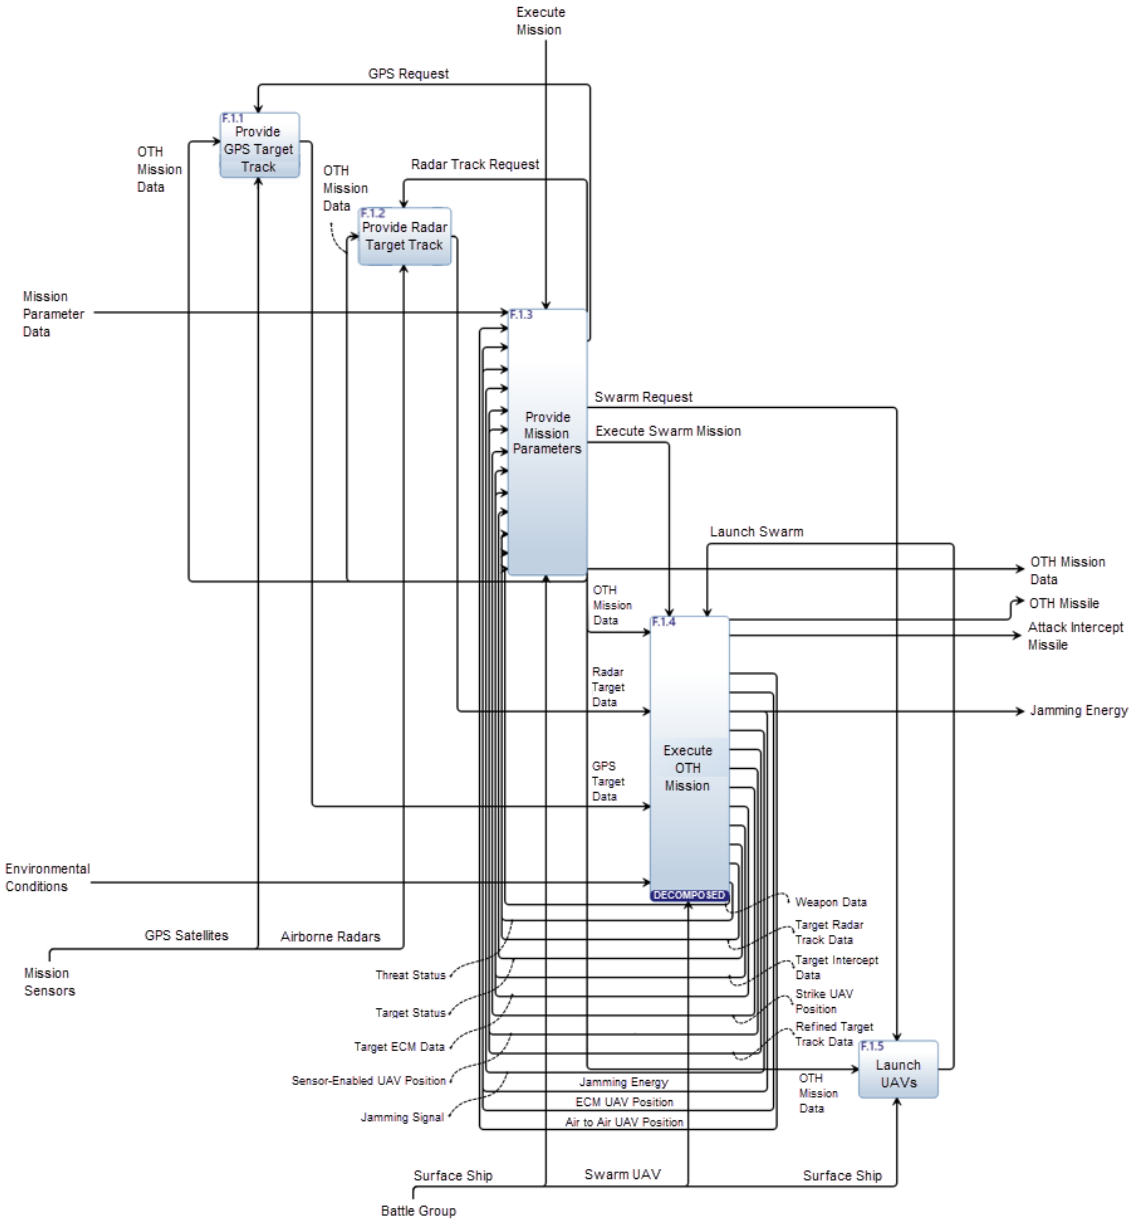

Figure 5. IDEF0: External System Diagram—External Mission Elements

1764 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

4. Level F-2 IDEF0 Sub-function Execute Mission Diagram

The interactions between the swarm assets required for mission execution are shown in Figure 6.

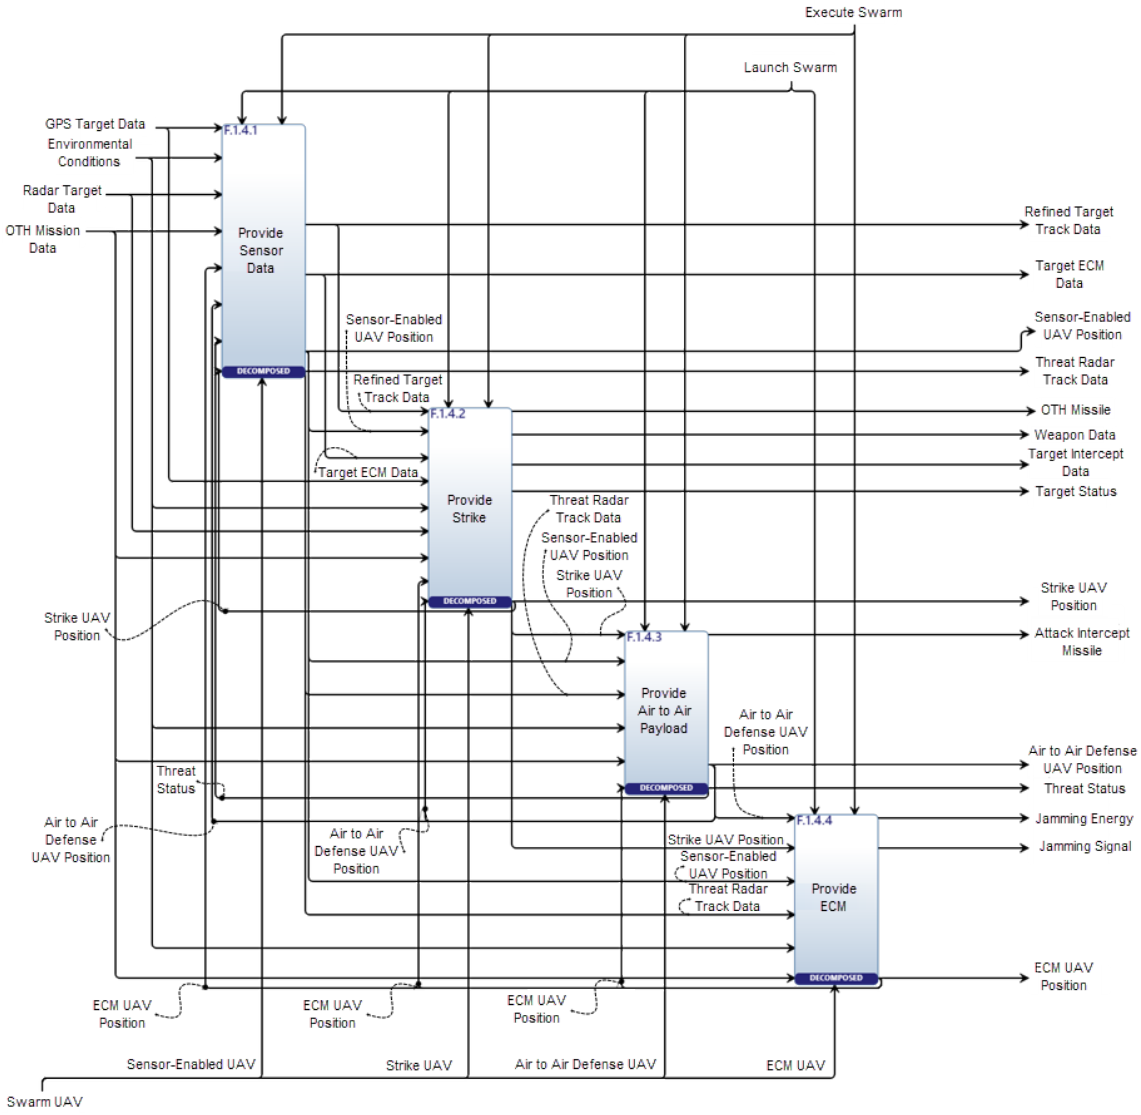

Figure 6. OV-5b: Execute Mission Context Diagram

1765 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

5. Level F-3 IDEF0 Sub-function Decompositions

The BREM Swarm Execute Mission diagram was decomposed to its sub-functions to provide a better understanding of the UAV sub-systems. All of the UAV decompositions have a fly UAV function by necessity and for completeness, but the UAV functional decomposition focused on the unique UAV configuration functions needed to support the mission execution. This approach dictates the specifics for the command and control of the UAV concerning flight operations as they were combined into the single function by design. Note each UAV possesses a communications function responsible for receiving and transmitting data to elements external to the UAV. The communications function was also bundled to capture the need for an encrypted data link.

6. Level F-3 IDEF0 Sub-function of Sensor-Enabled Unmanned Aerial Vehicle

The decomposition of the sensor-enabled UAV operation describes the interfaces and functions that enable the mission execution to have radar sensor capability. The sub-functions include producing radar energy, detecting radar energy, identifying incoming threats, and determining target location. These functions describe the sensor-enabled UAV capability to produce refined target measurements as well as threat data that will be used by other UAVs in the swarm. They also identify the radar signals needed to support the sensor-enabled UAV functions within the swarm. See Figure 7 for a depiction of the interactions between sensor-enabled UAV's sub-functions.

1766 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

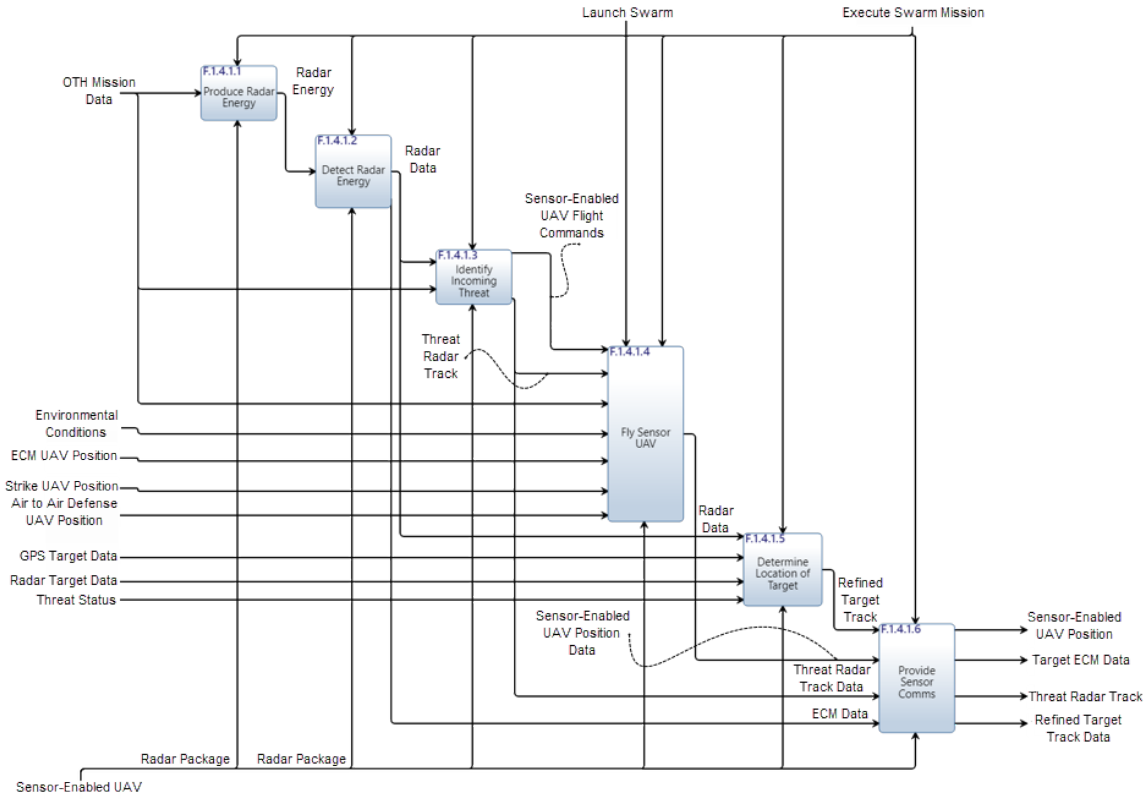

Figure 7. OV-5b for Sensor-Enabled UAV System Sub-functions IDEF0

1767 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

7. Level F-3 IDEF0 Sub-function of Strike UAV

The decomposition of the strike UAV operation describes the interfaces and functions that enable the mission execution to have strike capability. The sub-functions are track target, identify target intercept, launch ordinance, and provide kill assessment. These functions describe the strike UAV capability needed to complete the OTH strike part of the mission. While the swarm is designed to increase the overall mission success, the strike UAV is solely responsible for the delivery of ordinance to the mission target. See Figure 8 for a depiction of the interactions between the strike UAV's sub-functions.

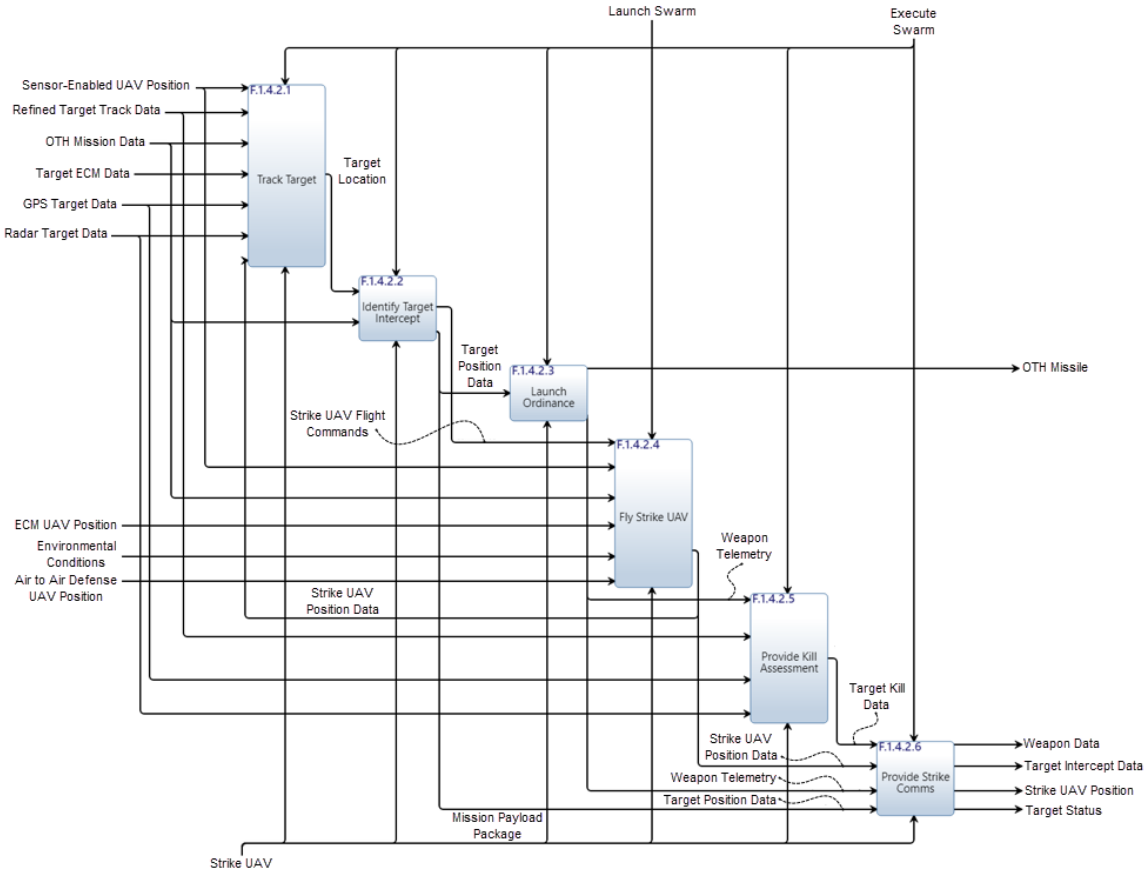

Figure 8. OV-5b for Strike UAV System Sub-functions IDEF0

1768 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

8. Level F-3 IDEF0 Sub-function of Air-to-Air Defense Unmanned Aerial Vehicle

The decomposition of the air-to-air defense UAV operation describes the interfaces and functions that enable the mission execution to have an air-to-air defensive capability. The sub-functions are track inbound threat, identify threat intercept point, launch a missile, and assess threat status. These functions describe the air-to-air defense UAV capability needed to provide the swarm with an air-to-air intercept operation. By eliminating possible threats to the swarm, the overall mission success is improved. See Figure 9 for a depiction of the interactions between the air-to-air defense UAV's sub-functions.

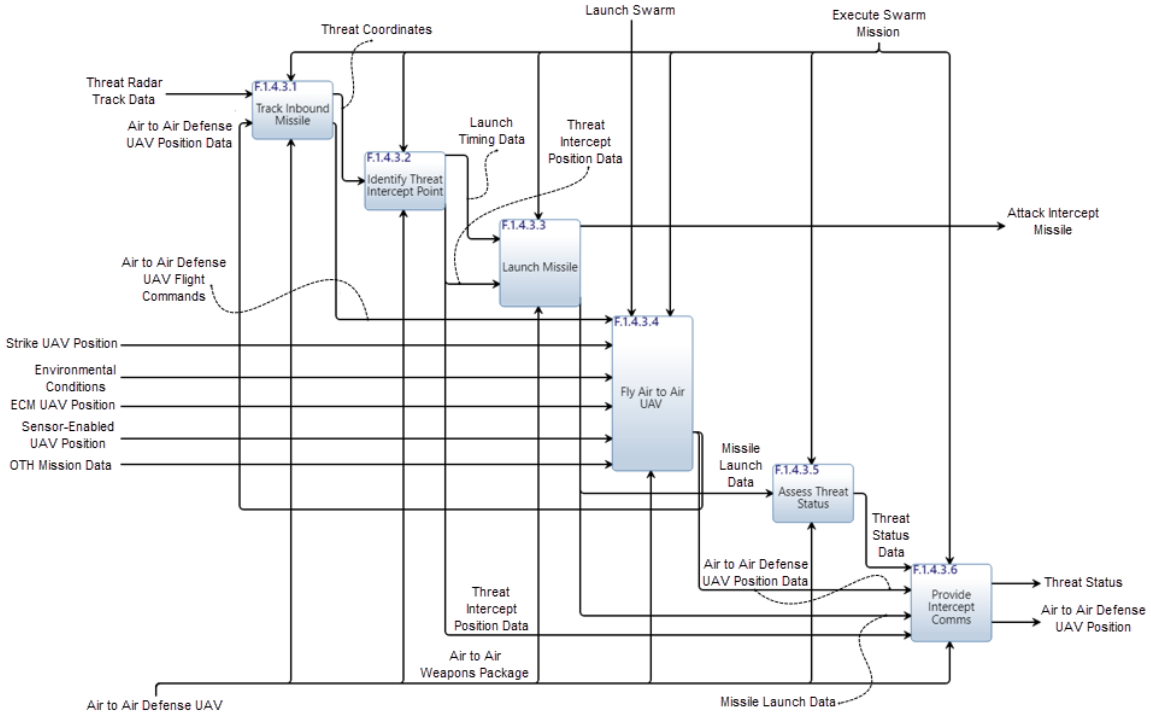

Figure 9. OV-5b for Air-to-Air Defense UAV System Sub-functions IDEF0

1769 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

9. Level F-3 IDEF0 Sub-function of ECM UAV

The decomposition of the electronic countermeasure (ECM) UAV operation describes the interfaces and functions that enable the mission execution to have an ECM defensive capability. The sub-functions include calculating the jamming position and providing the jamming signal. These functions describe the ECM UAV capability needed to provide the swarm with a radar jamming operation. A jamming capability within the swarm can reduce the probability of success for an incoming threat. Decreasing the likelihood of success that a UAV in the swarm is damaged will help improve the probability of success for the overall mission. See Figure 10 for a depiction of the interactions between the ECM UAV's sub-functions.

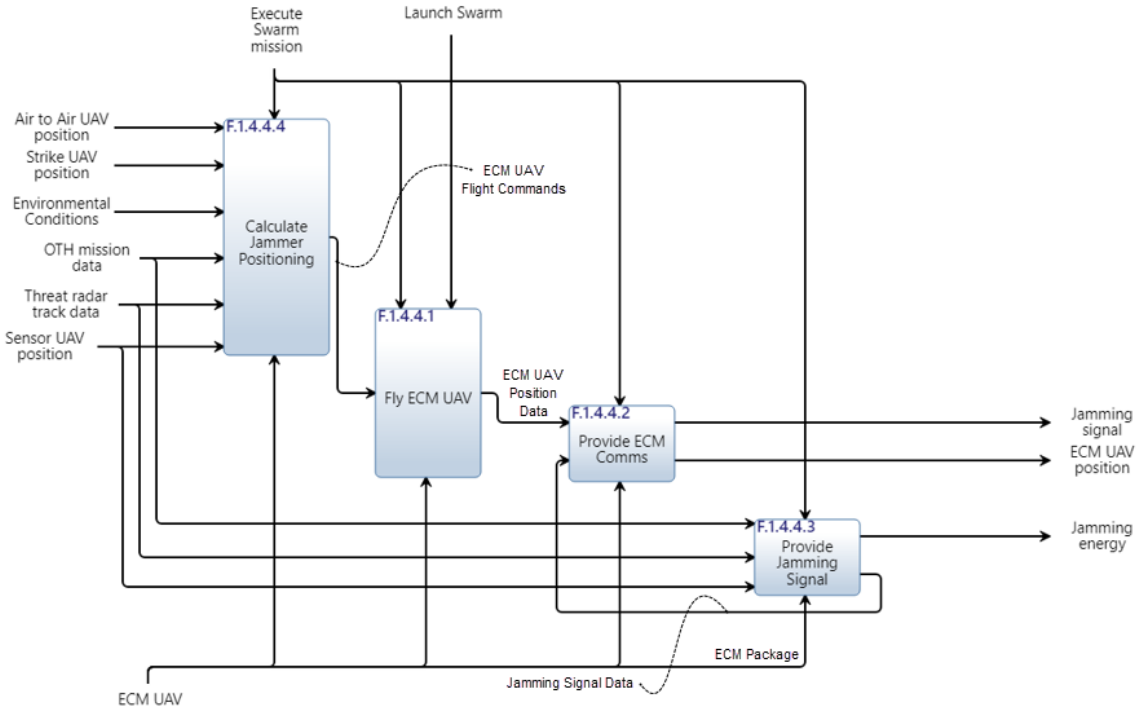

Figure 10. OV-5b for ECM UAV System Sub-functions IDEF0

1770 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The F-3 level of decompositions provides an understanding of the individual UAV capabilities supported through the UAV functional decompositions. This breakdown aided in identifying the sensor, strike, air-to-air, and ECM functions needed to develop the swarm capability. After several iterations of the decomposition, the UAV sub-functions can provide further fidelity in the development of the system architecture. They help define the swarm capabilities as needed to support the mission execution from a unique UAV mission package.

10. OV-6c: Event Trace Description

The OV-6c diagram traces the actions that occur in a given scenario or sequence of events. It provides a time-ordered examination of the resource flow for the swarm scenario as well as the tracing of actions in a critical sequence of events. The mission execution capability is modeled by the set of activities and their attributes. The event trace description captured focuses on the sequence of events completed by the swarm during the execution of the OTH strike mission. It establishes the inter-swarm events by describing the UAV to UAV interactions needed for the execution of the OTH mission. This event trace will be leveraged for the development of the modeling and simulation part of the project. The event trace diagram is shown in Figure 11.

1771 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

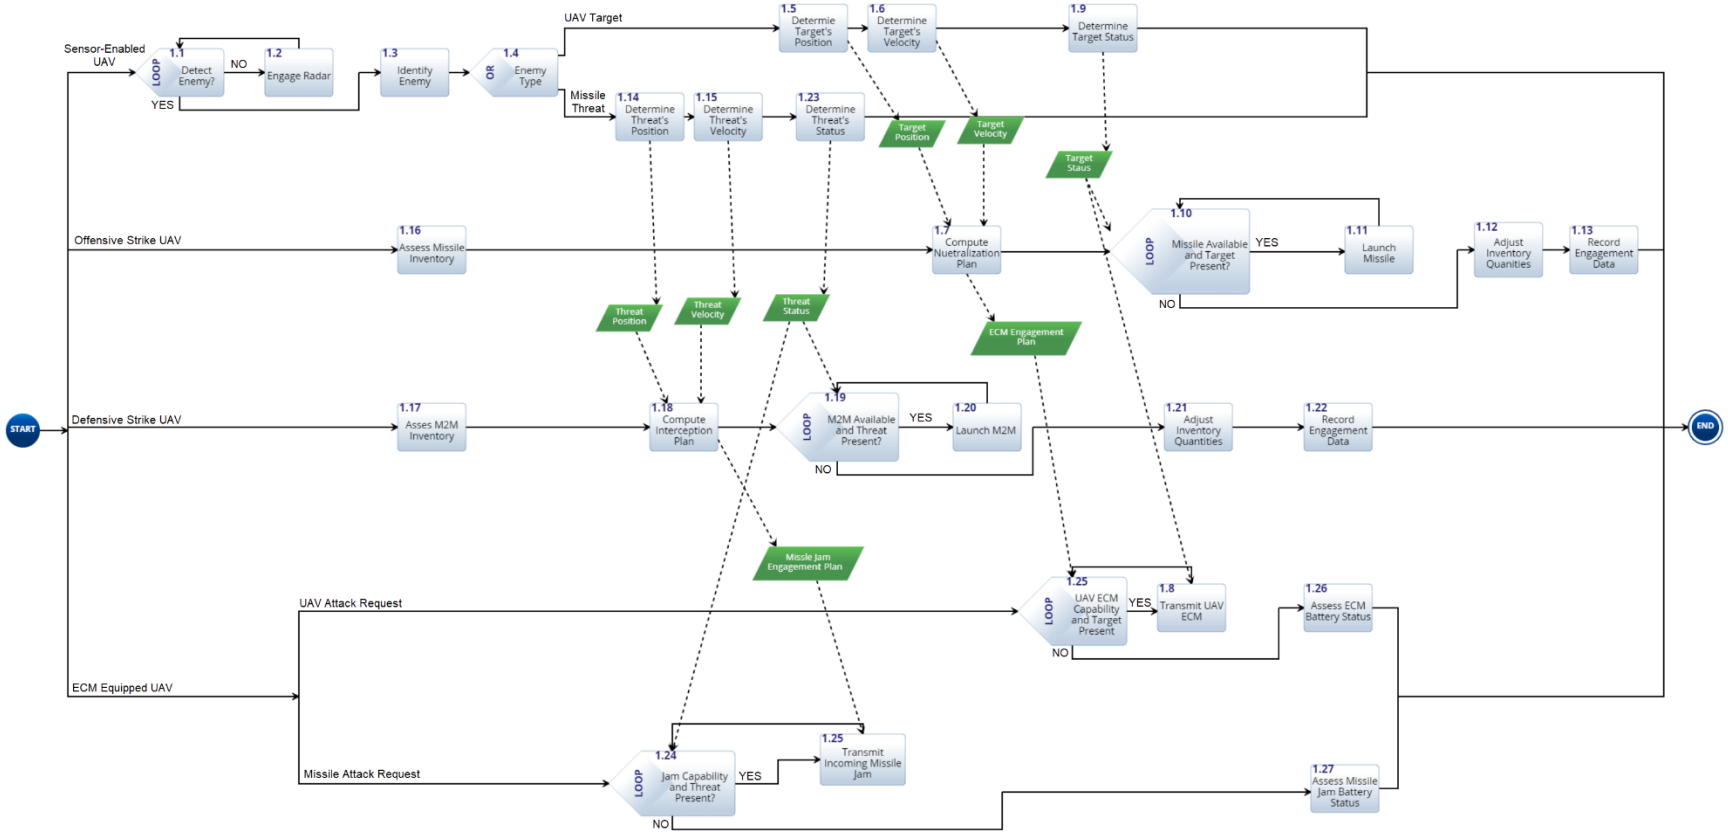

Figure 11. OV-6c Event Trace Description

1772 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

C. SYSTEM ARCHITECTURE

Systems architecture view (SV) describes the system of concern and the connections among the system and subsystems in context with the operational view. The SV allows for evaluation of system operational requirements, evaluation of interoperability issues, and system baselining. As a group, we decided to showcase our system through the use of an SV-1, SV-2, and SV-4 diagram.

1. SV-1: Systems Interface Description

The SV-1 in Figure 12 visualizes the interconnections between the system and its subsystems. The SV-1 depicts the sharing of information between the battlegroup assets. Note the surface ship is acting as a vital node in the relay of this information. The surface ship collects data from GPS satellites, airborne radars, and the UAV swarm. In return, the surface ship relays collected information to each asset as needed. Together, each asset, including the surface ship, is more aware of potential threats in the battlespace than any one asset would be otherwise.

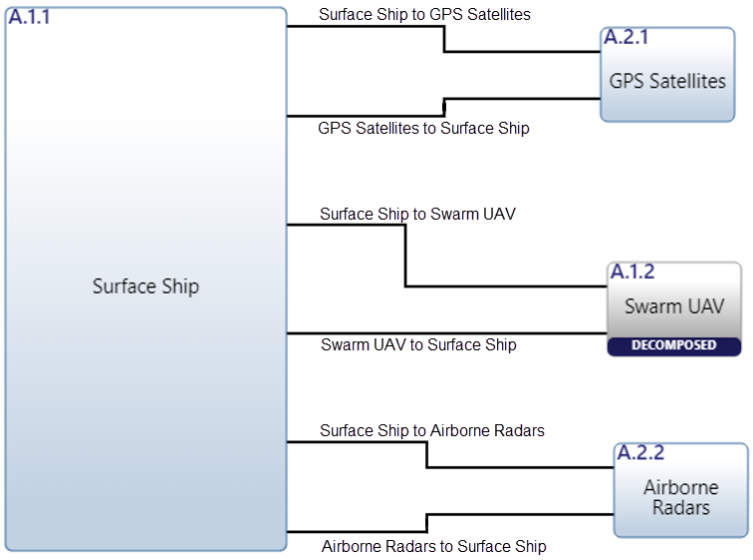

Figure 12. SV-1: Systems Interface Description

1773 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

2. SV-2: Communications Network Diagram

The SV-2 depicted in Figure 13 details the lines of communication between the swarm assets. Note each UAV is connected to the other three UAVs through a secure data link, which allows information sharing to prevent UAV isolation should any UAV be lost to an incoming threat. The network design also allows information to be relayed between UAVs to maintain situational awareness even when assets are spread across the battlespace.

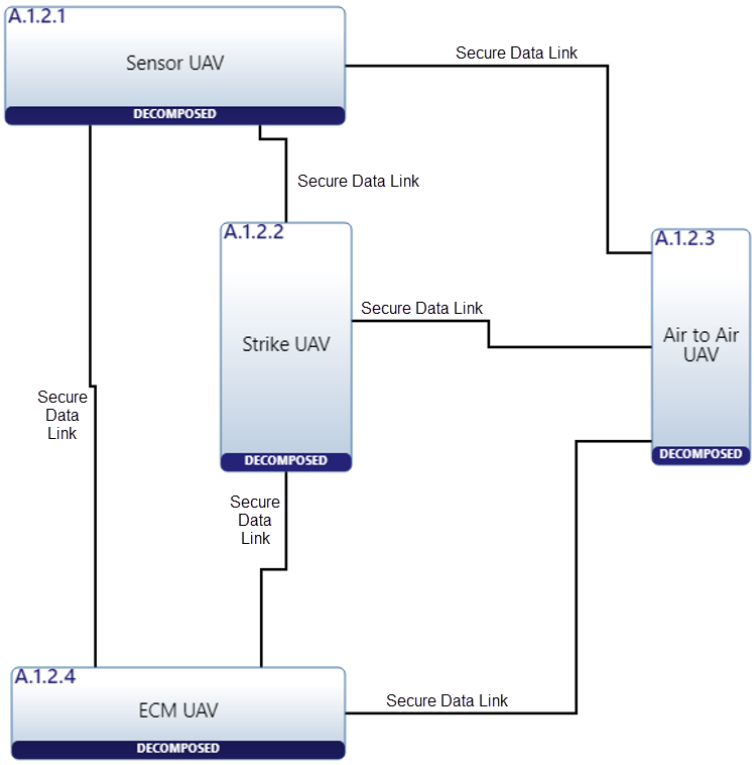

Figure 13. SV-2: Communications Network Diagram

1774 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

3. SV-4: Functional Hierarchy

The SV-4a depicted in Figure 14 details the functional relationships required to support the over-the-horizon mission. Execution of the over-the-horizon mission is supported by the principle functions of the UAVs, which include providing sensor data, strike capability, air-to-air payload, and electronic countermeasures. Each principle function is decomposed to identify the required subfunctions.

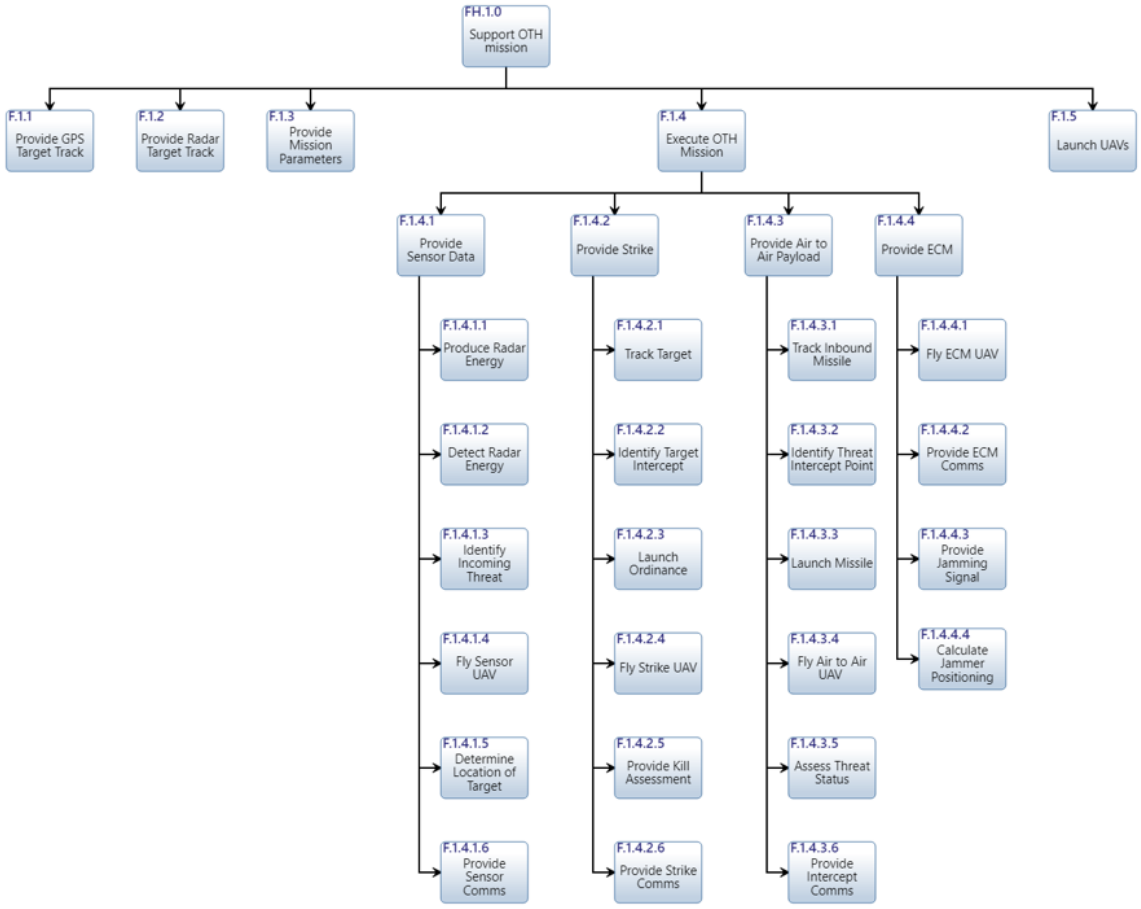

Figure 14. SV-4a: Functional Hierarchy

Reflecting on Chapter III, the operational and system architecture defined to illustrate the relationships required between the swarm assets for mission execution. Chapter IV will culminate the buildup of previous chapters with the modeling and simulation of the OTH mission execution by the UAV swarm.

IV. MODELING, SIMULATION, AND, OTH MISSION ANALYSIS

This chapter describes the modeling and simulation (M&S) analysis of the system of UAV systems (referred to as the "swarm") for the OTH mission. It includes a look at cost factors for the utilization of UAVs in the execution of the OTH mission. The chapter contains an overview of the M&S effort and a description of the OTH mission analysis methods employed. The purpose of the model, as well as the model's limitations, will be discussed and followed by a review of the data derived from the model; a similar discourse will follow for simulation development. The execution of the OTH mission using UAVs will then be assessed from a cost-effectiveness standpoint with manned platforms.

A. PURPOSE OF THE MODELING, SIMULATION AND MISSION ANALYSIS

The goal of the M&S and mission analysis was to study the operational benefits of adding UAVs to the OTH mission. The M&S analysis assessed the individual UAV performance factors that are drivers for the OTH mission success. A blue force versus red force OTH mission scenario was modeled. The blue force was equipped with four different types of UAVs: sensor-enabled, air-to-air (A/A), electronic countermeasure (ECM), and strike. The red force consisted of a ship that could return fire with its own set of OTH weapons. The red force ship was the OTH target of the blue force. Mission success consisted of eliminating the red force ship. The performance values of the blue force's individual UAV types were varied, and different combinations and configurations of UAVs were modeled. The cost of the UAV mission implementation was assessed as well.

1. Modeling and Simulation Approach

The approach for the M&S effort is shown in Figure 15. A single scenario for the OTH target mission execution was captured. Then a probabilistic model called the swarm Strike Model (SSM) and the Swarm Strike Simulation (SSS) was developed to represent an instance of the scenario. The results from the SSM and the SSS were compared to establish confidence in the M&S effort. The performance data was then used to analyze the

1777 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

execution of the OTH scenario. This analysis was used to provide evidence for making recommendations about the use of UAV for OTH mission execution.

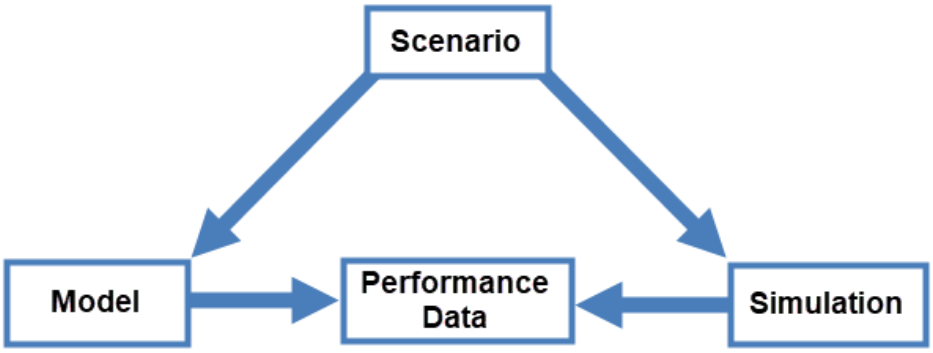

Figure 15. Modeling and Simulation Scenario

2. Modeling and Simulation Scenario

A mission scenario was chosen that represented a blue force OTH strike using a variety of UAV assets onto a red force ship, referred to as the "OTH target." The red force was equipped with its own OTH weapons to fire at the blue force UAVs. Figure 16 is an illustration of the scenario.

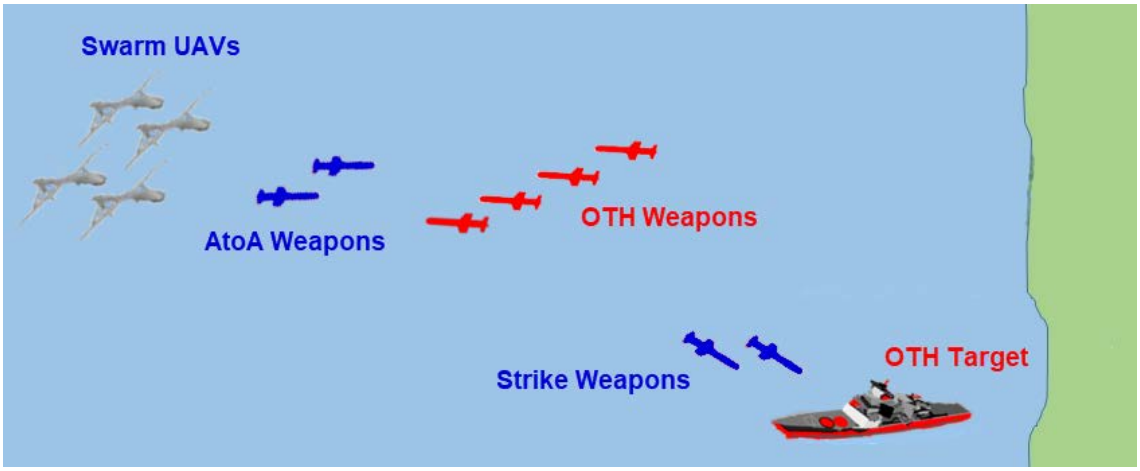

Figure 16. UAV Swarm Engagement Scenario

1778 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The M&S efforts leveraged the UAV types described in the CONOPs and the UAV functional descriptions in the DoDAF architectures. In the mission scenario, the red force "OTH target" can fire on the swarm UAVs during the execution of the OTH-S mission. The scenario outcomes capture the OTH target kill as well as the number of swarm UAVs lost to hostile fire. Successful swarm engagement is defined by the elimination of the OTH target while minimizing swarm UAVs lost to hostile fire. Two critical probabilities were leveraged to evaluate the OTH-S mission success: the probability of striking the OTH target and the probability of a swarm UAV being hit. These two probabilities were central to the series of experiments executed to determine the impact of swarm configurations and UAV performance parameters on engagement success.

The scenario shown in Figure 16 was used to develop the M&S capability. The scenario captures the engagement of the swarm by hostile OTH weapons, as shown in the middle of Figure 16. The inbound threats may be intercepted by the A/A UAV's weapon loadout. The remaining OTH weapons, if any, may be defeated by the jamming energy of the ECM UAV when the ECM UAV is included in the swarm configuration. Any OTH weapons that survive intercept and jamming attempts will have the opportunity to kill a swarm UAV. If the Strike UAV survives the OTH weapons engagement, the UAV will release the strike weapons on the OTH target, as shown in the lower right of Figure 16. The strike weapons will be aided by the sensor-enabled UAV when present in the swarm. Elimination of the OTH target is considered a mission success. Note the scenario detailed above assumes the OTH target environment does not include any factors inhibiting swarm performance.

3. Modeling, Simulation, and Data Analysis Tools

The SSM used for assessing the OTH mission was developed in Excel. This model uses several of the built-in Excel functions including the random number generator and the Binomial Inverse Function, which returns the inverse of the Cumulative Binomial Distribution for a given number of independent trials. These functions allow for probabilistic evaluation of the OTH engagements. The SSM also used the Visual Basic (VB) software in Excel to automate the generation and collection of the swarm

1779 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

configuration data. The SSM's VB script runs every allowable swarm configuration and captures the probabilities affecting mission success for each run.

Confidence in the SSM was increased upon comparing the results from the SSM to those obtained from the SSS. The SSS created for this purpose, which was developed in ExtendSim, captures a time-based execution of the OTH mission scenario. The ExtendSim functions for normal distribution time delays, random number generation, and probabilistic branch selection were used to produce the metrics required for comparable assessment of the OTH scenario.

The M&S effort used both the Excel and Minitab statistical analysis tools to assess data generated. Excel was used to calculate the variance and confidence intervals for the data produced by the SSM. The statistical tools in Minitab were used to generate the design of experiments for the UAV performance parameter analyses. Minitab was also used to generate the main effects analysis using the data from the design of experiments (DOE) executions. The role of each tool in the M&S effort is summarized by the flowchart shown in Figure 17.

1780 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

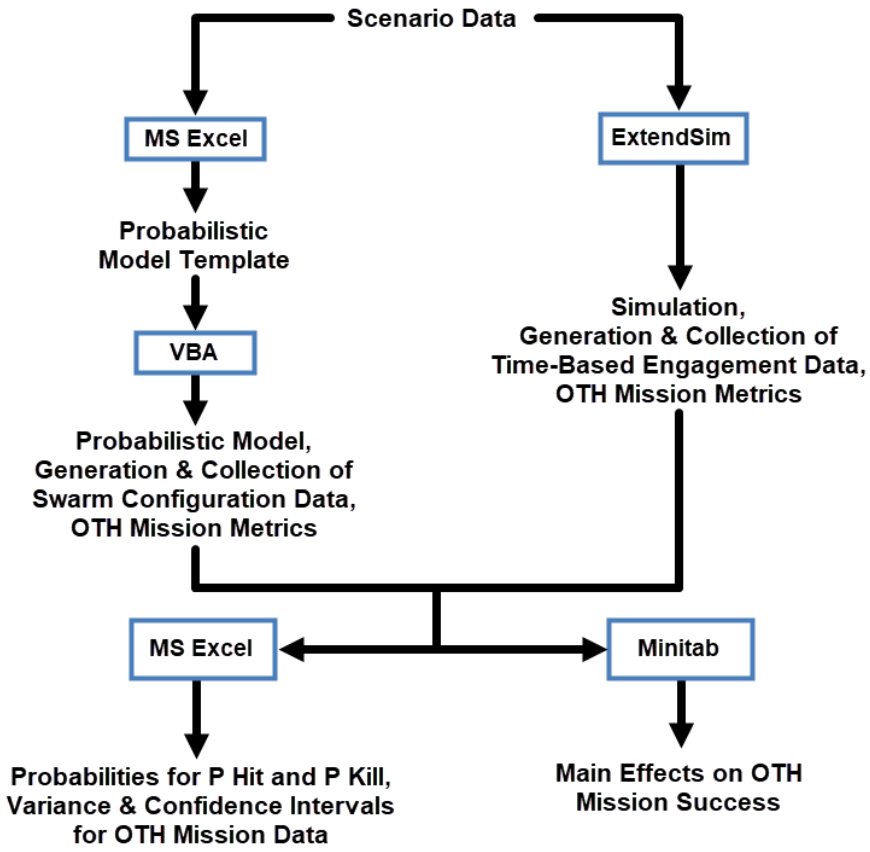

Figure 17. Modeling and Simulation Flowchart

4. Assumptions and Constraints

Several assumptions were made at the onset of the project. For instance, the scenario assumes a single hit to a swarm UAV, the OTH target, or OTH weapon will result in a kill of the targeted asset. In addition, the OTH target position is assumed known prior to swarm launch and will not loiter outside the effective range of the swarm. Note the current SSM and SSS builds neglect adverse effects in the OTH target environment, such as severe weather and geographical influences. Swarm UAV reliability is also neglected.

Both SSM and SSS are constrained to a single OTH target engagement per scenario execution. The OTH weapon performance, percent of kills per engagement, is defined in terms of threat probability of kill (threat P_k) in both the SSM and SSS. Threat P_k in the M&S was held constant at 70 percent throughout scenario execution. The SSM was constrained to having a maximum of five of each UAV type in the mission. This was done

1781 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

to manage the complexity of the SSM in relation to its capability for assessing swarm sizes. One functional constraint is that the SSM does nothing to prevent the OTH weapons from targeting the same UAV multiple times. The SSS was developed to have a single configuration of each UAV in the swarm during the scenario execution. This was done to manage the complexity of the SSS and focus on the assessment of the UAV specific performance factors.

5. Modeling and Simulation Capabilities

The M&S effort developed both the SSM and the SSS as a means to provide more fidelity in the OTH mission analysis. A full comparison of the SSM versus the SSS capabilities is shown in Table 3.

Table 3. M&S Capability Comparison

Capability	Modeling	Simulation
UAV performance factors	Included	Included
Swarm UAV configurations	Variable	1 each
OTH target	Single	Single
OTH target weapons loadout	Variable	Set to 4
OTH weapons targeting order	Based on RCS	Based on RCS
OTH weapons targeting fidelity	Low	Medium
OTH weapon performance	Set to 70%	Set to 70%

The low assessment for the SSM targeting fidelity reflects a limitation inherent to the model that allows the continued targeting of a downed UAV. The model's targeting fidelity is further reduced by the instantaneous assessment of all engagements, which negates the effects of volley timing and follow-on target selection. The SSS targeting fidelity was assessed as medium due to the inclusion of a timing component. The timing component allowed for the downing of the A/A or ECM UAV at mission onset. The loss of these UAVs decreased the swarm's defensive capabilities and the OTH weapons were able to target another UAV with a greater kill probability. The SSS targeting fidelity was not assessed as high due to the complexity preventing multiple swarm configurations to be

1782 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

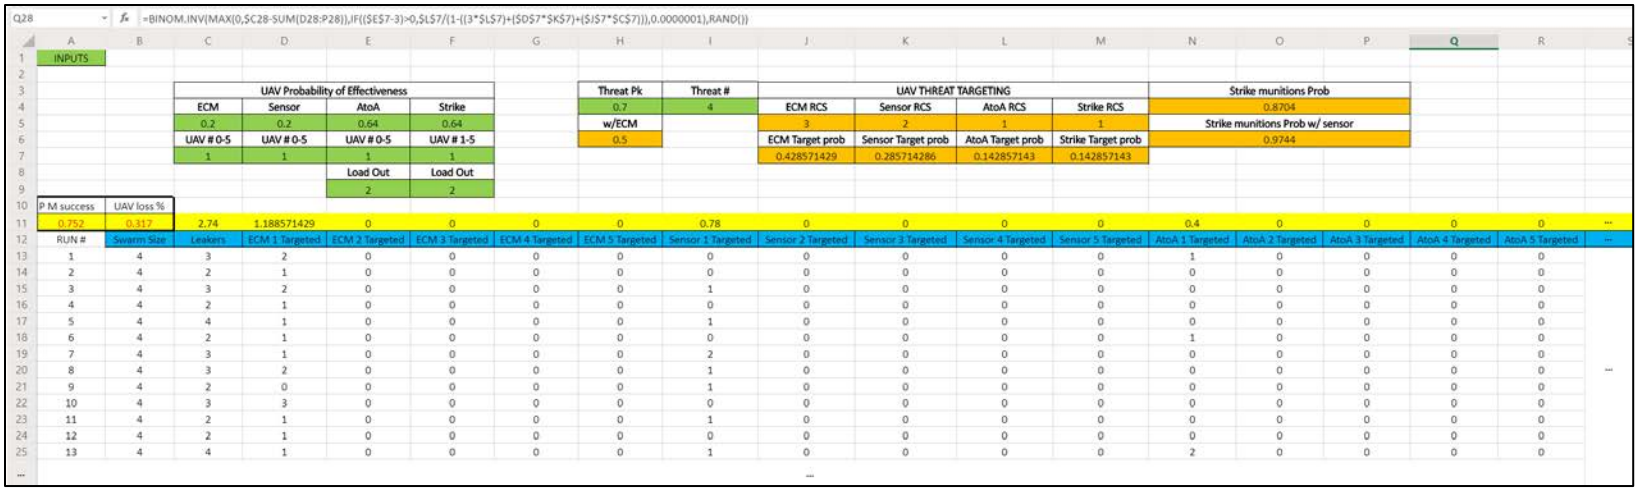
readily assessed. As such, only one UAV of each type was represented in the swarm configuration for the simulation effort.

B. DESCRIPTION OF THE MODEL

1. Model Parameters

Weapon performance values are integral to the UAV performance analysis and drive the target kill assessment. The success of a weapon's engagement is quantified by the probability of target intercept, the probability of target elimination upon intercept, and the overall weapon reliability. Factors affecting the performance of assets assigned to the Strike and A/A UAVs are accounted for in their respective success probabilities. Factors affecting the probability of effectiveness for the sensor-enabled and ECM UAVs are accounted for in each UAV's net contribution to the swarm. The sensor-enabled UAV's probability of effectiveness reflects the UAV's ability to enhance the intercept of A/A UAV's intercept of OTH weapons as well as the Strike UAV's probability of OTH target hit. Likewise, the EMC UAV's probability of effectiveness reflects the UAV's ability to degrade the performance of inbound OTH weapons. The M&S efforts did not account for factors affecting UAV reliability, thereby allowing for an engagement success value of 1. Known reliability events could be integrated by multiplying the engagement probabilities by the reliability value of the swarm UAV.

Using the CONOPs and system architecture developed for the OTH mission as a foundation, the team developed the SSM for the swarm OTH engagement scenario. The SSM allows for the assessment of swarm size and selection of UAV assets as well as analysis of individual UAV performance. These metrics are captured in the SSM and expressed in terms of probability of relative success.



There are several probability factors included in the SSM, such as the probabilities for targeting order for OTH weapons. The UAV targeting probabilities are based on assumptions developed from a radar cross-section (RCS) analysis of the UAVs. An inbound OTH weapon is expected to target the ECM UAV with the sensor-enabled UAV being the next likely target. The remaining OTH weapons would give the A/A and strike

1783 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

UAVs equal priority. The ECM UAV is thought to be the priority target for the OTH weapons as the UAV's escort jamming capability is most effective with the UAV in front of the swarm. The ECM UAV is likely the first UAV targeted by the OTH weapons due to its jamming signal transmission and lead formation position. The sensor-enabled UAV's employment of radar to enhance the OTH firing solution also generates considerable radar signature thereby placing the UAV next OTH weapon's targeting order. The A/A and strike UAVs have a similar configuration and asset loadout, which allows the UAVs to share the lowest position in the targeting order.

The probability that a hostile force would target and eliminate a swarm UAV is dependent on the engagement values and performance of the OTH weapons. Successful engagement of the A/A weapons reduces the number of inbound threats. Likewise, the employment of the ECM UAV function minimizes the probability that a hostile threat will be successful in killing a swarm UAV. Once the probability of a successful OTH weapon engagement has been evaluated, and the fallout of the intercept attempt realized, the number of UAV casualties per scenario execution is used to determine the probability of the UAV hit (P_{Hit}) metric. Next, the SSM predicts the success of the OTH target kill using the remaining strike UAVs weapons available. The OTH target kill success is used in the calculation of the probability of success ($P_{Success}$) metric. An excerpt from the SSM is shown in Figure 18.

Figure 18. Swarm Strike Model Excerpt

1785 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The orange boxes shown in Figure 18 highlight the calculated values used in the execution of the scenario. These values are not altered by direct input; however, several values are linked to input values and may vary as a result. The targeting probability values, shown below the probability cells, are mathematically defined by RCS in the targeting process.

The UAV performance inputs and OTH weapons performance parameters are shown in Table 4. These values are also shown in the light green boxes of Figure 18. In addition to these values, the table captures the allowable range for the SSM inputs.

Table 4. Swarm Strike Model Input Parameters

UAV Probability of Effectiveness				
	ECM	Sensor	A/A	Strike
Range	0.01-0.99	0.01-0.99	0.01-0.99	0.01-0.99
	Swarm Configuration			
	ECM	Sensor	A/A	Strike
Range	0-5	0-5	0-5	1-5
	UAV Weapons		OTH Weapons	
	Strike Loadout	A/A Loadout	Threat Pk	Threat Load-out
Range	0-4	0-4	0.7	0-4

The range values shown in Table 4 were used to calculate asset-specific probabilities. While the full range shown in Table 4 is allowed in the SSM execution, the probability of effectiveness for a given platform is bounded by operational effectiveness parameters as well as reliability factors. These bounds were defined by the performance assessments conducted on each UAV platform. The number of weapons a UAV may carry is not mathematically restrained in the SSM; the values shown reflect the range considered for the scenario assessment. Once the SSM functionality was confirmed, a study of the output variance was conducted to assess the consistency of the results.

The data in Table 5 shows the variance in the SSM outputs for $P_{Success}$ and P_{Hit}.

The number of model trials was gradually increased from 100 to 500 runs per engagement. All inputs for the SSM were held constant during the increase of trial runs. A selection of 20 samples was collected at the higher trial count for statistical analysis. As shown in Table 5, the observed variance decreases as the number of trial runs increases per

1787 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

engagement. The variances were then used to calculate the 95 and 99 percent confidence intervals. The benefit of adding additional trial runs on $P_{Success}$ output decreases significantly from 350 to 500 runs. Based on the minimal difference in obtained data and the increased time required to run the SSM, a run size of 350 was selected for the remaining analyses.

2. Model Runs for UAV Performance Factors

The SSM established six UAV performance factors. The ECM and sensor performance, as well as loadout, A/A, and strike weapon performance, were assigned values of estimated effectiveness on a scale from zero to one; a value of zero represents no effect and a value of one would be completely effective. For instance, an effective range of 0.20 to 0.50 was estimated for the ECM UAV while the sensor UAV was assigned an effective range of 0.20 to 0.50. Using the six UAV performance factor inputs to the SSM, a 2-level factorial design of experiments (DOE), with a 1/8 fraction and a single center point per cube, was developed. The performance modeling inputs and outputs for the DOE are captured in Table 6.

Table 6. UAV Performance Modeling DOE

P_{ECM}	P_{Sensor}	$P_{A/A}$	P_{Strike}	Strike Loadout	A/A Loadout	$P_{Success}$	P_{Hit}
0.20	0.50	0.64	0.64	4	1	0.723	0.391

1788 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Referring to Table 6, the ECM P-value relates to the degradation in the performance of an inbound OTH weapon as caused by the ECM UAV. On the offensive, the sensor performance (Sensor P) value represents the enhancement of the strike weapon's performance afforded by the sensor-enabled UAV. The A/A and strike performance (Strike P) values represent the probability of hit for each weapon in the A/A and strike UAV loadout. The strike and A/A loadout values capture the total number of weapons in the swarm as equipped by the respective UAV platform.

The swarm configuration was maintained at one UAV of each configuration to ensure that multiple UAVs of the same platform did not weigh the performance parameters. The OTH weapons loadout was set to four to present a stressing engagement for the swarm. The results of the DOE were evaluated in Minitab. The main effects for the probability of OTH hit ($P_{Success}$) and the probability of UAV hit (P_{Hit}) are captured in Figures 19 and 20.

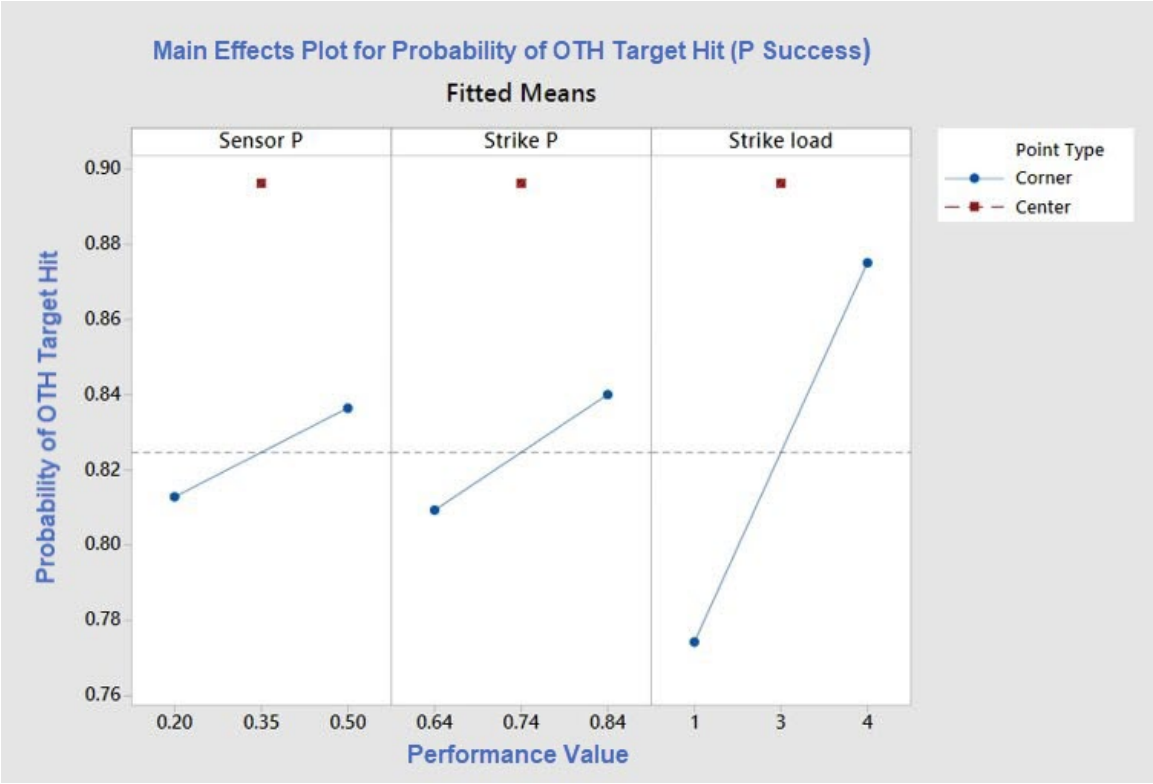

Figure 19. Engagement Probability of Success Main Effects

1789 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

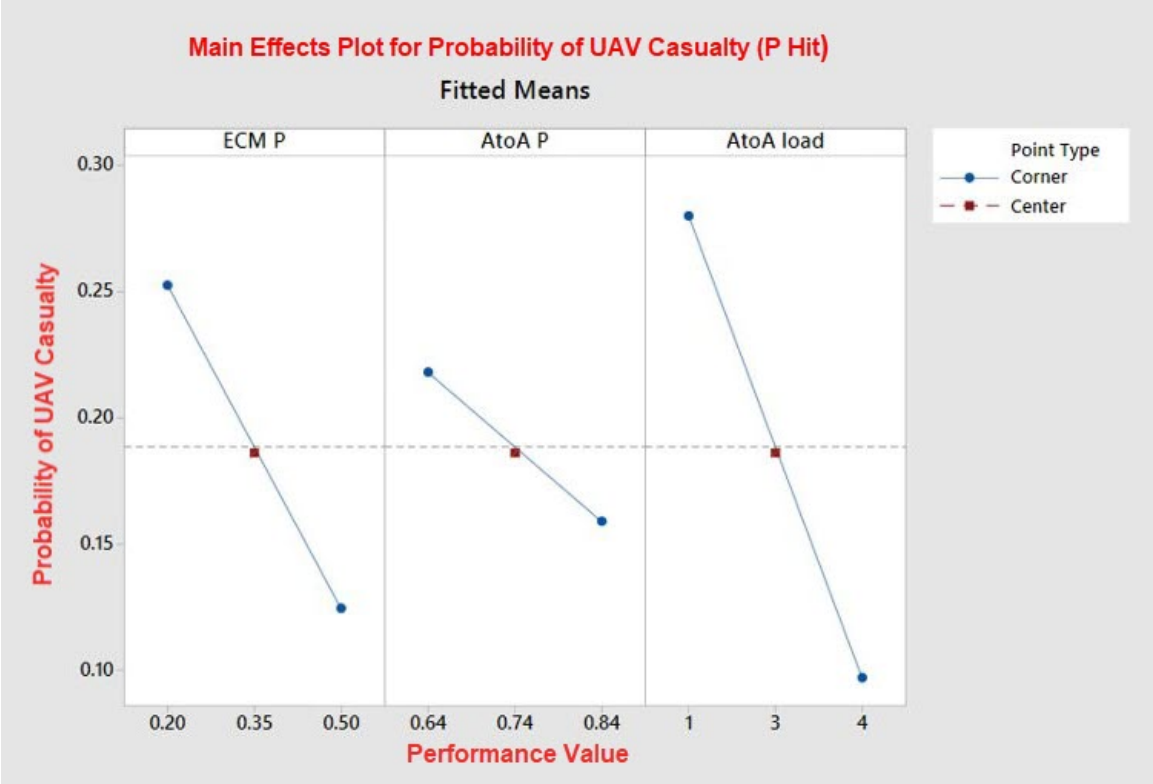

Figure 20. Engagement Probability of Hit Main Effects

The slope of the line in the main effects plots captures the impacts of the UAV performance factors on the engagement criteria. The plots show that increasing the strike loadout has the most significant impact on the probability of OTH hit. While increasing the A/A loadout has the most significant impact on the probability that a UAV is hit. The overall engagement was evaluated, and the SSM is predicting that UAV survivability is driving $P_{Success}$ for the OTH engagement.

3. Model Runs for Swarm Configurations

Utilizing the swarm configuration capability of the SSM, a two-level factorial DOE with a 1/8 fraction and a single center point per cube, for the swarm size was developed in the Minitab software tool. The model inputs and outputs for the swarm size DOE, shown in Table 7, cover the analysis of a mission where the OTH target has a loadout of four weapons.

0	5	5	1	0.963

1791 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The combination of each of the UAV configuration numbers equates to the total swarm size for the engagement. The performance inputs remained constant at 0.2 for the ECM and sensor, while the A/A and strike weapons performance values were set to 0.64. The A/A and strike loadouts were set to two each. The swarm size was evaluated for an OTH weapons loadout of zero, or non-stressing, and loadout of four, a highly stressing engagement. The results of the DOE were evaluated in Minitab. The following three figures capture the main effects for the probability of OTH hit ($P_{Success}$) based on the red force OTH loadouts of zero (shown in Figure 21) and four (shown in Figure 22) as well as the probability of UAV hit (P_{Hit}) for an OTH loadout of four (shown in Figure 23).

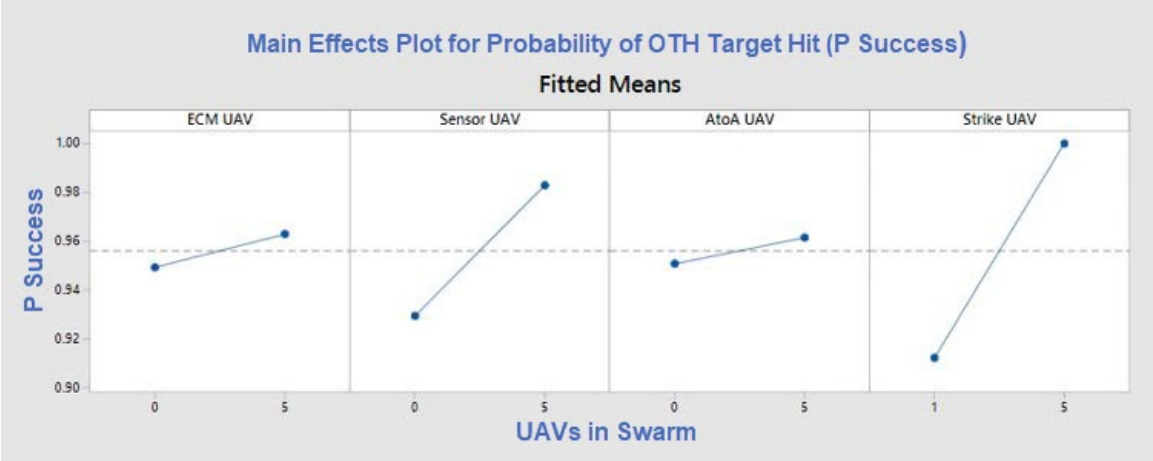

Figure 21. Probability of Success Main Effects for Red Force with No Return Fire Capability

The main effects plots for the modeling parameters show the strike UAV is the performance driver for the scenario in which the red force has no return fire capability. The A/A and ECM UAVs have a negligible impact in this scenario since there are no OTH weapons to act upon.

1792 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The main effects plot in Figure 22 shows all UAV configurations are significant in the scenario where the red force can return fire using four weapons. As seen in Figure 22, increasing the number of strike UAVs has the most significant positive impact on mission success. A swarm consisting of five strike UAVs provide additional opportunities for engagement of the OTH target. However, a UAV swarm consisting solely of strike UAVs is more susceptible to casualties and is not ideal.

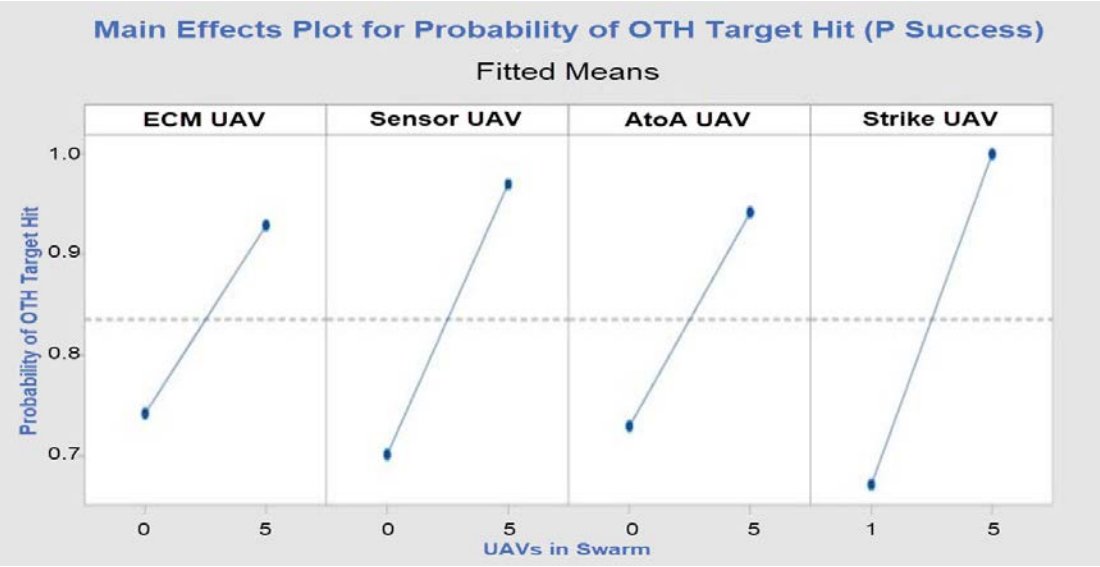

Figure 22. Probability of Success Main Effects for Red Force with Four Return Fire Weapons

The main effects plots in Figure 23 show that the UAV hit (P_{Hit}) performance driver for the four fire OTH engagement is the A/A UAV. The sensor and strike UAVs have an equivalent impact on P_{Hit} due to the constant OTH weapons having an increasing number of targets. However, increasing the number of A/A UAVs has the most significant positive impact on the P_{Hit} criteria for mission execution.

1793 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

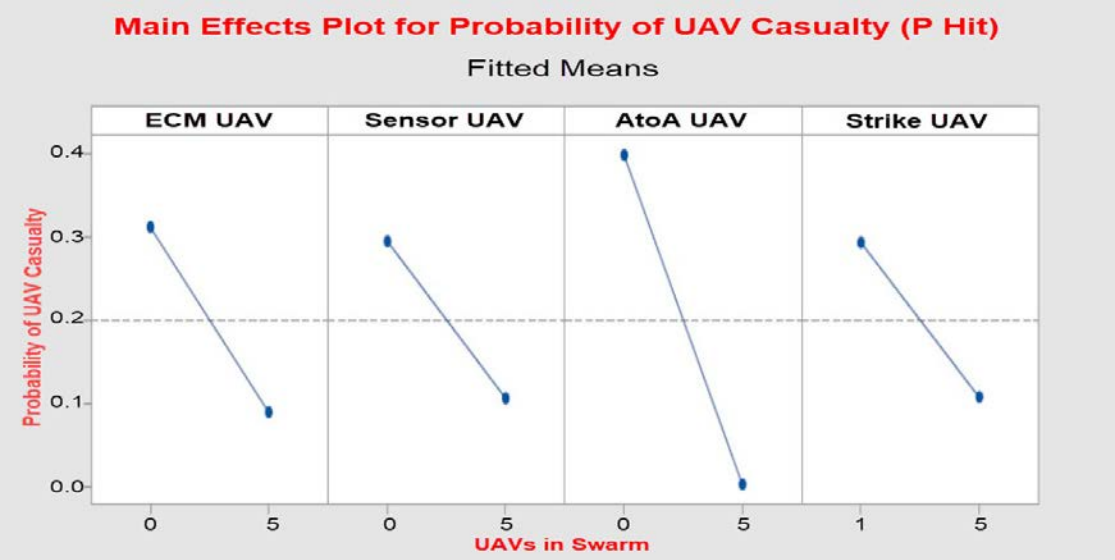

Figure 23. Probability of Hit Main Effects against Red Force with a Return Fire Capability of Four Weapons

4. Lookup Table Model of Swarm Configurations

The SSM was also used to produce a table of swarm configurations as a lookup table for the execution of a set of OTH engagements, as shown in Table 9. This table was developed by evaluating the OTH return fire capability shown in the threat column. The swarm configurations were chosen by maximizing the probability of OTH hit ($P_{Success}$) while minimizing the values of UAV hit (% UAV loss) and reducing the UAVs committed to each engagement to ensure the highest number of missions could be completed.

Table 9. Swarm Configuration for OTH Engagement

Threat No.	ECM No.	Sensor No.	A/A No.	Strike No.	$P_{Success}$	P_{Hit}	Swarm Size
0	0	1	0	1	0.986	0.000	2
1	1	1	1	1	0.963	0.014	4
2	0	1	1	2	0.971	0.119	4

3	0	1	2	2	0.974	0.081	5
3	1	1	1	2	0.974	0.175	5
4	0	1	2	2	0.969	0.170	5
4	1	1	1	2	0.966	0.260	5

1794 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The data in Table 9 represents the recommended swarm sizes for deployment against OTH targets that have a known return fire capability. For an OTH target without return fire capability, the SSM is predicting that a swarm configuration of one sensor and one strike UAV will have a 98% probability of target kill. The prediction for the stressing scenario includes two swarm configurations with good probabilities for the scenario metrics of $P_{Success}$ and P_{Hit}. The determining factor in using one swarm configuration over another is made when planning the likelihood of follow on missions. Choosing to deploy a swarm consisting of a single A/A UAV allows an additional OTH mission to be accomplished using an A/A UAV in the swarm.

C. SIMULATION ANALYSIS

The SSS executes the single OTH target engagement with the same mission performance parameter outputs as the SSM. The UAV performance simulation the SSS for the OTH engagement was developed to increase the fidelity of the performance data analysis. The OTH engagement in the SSS was developed in two parts. The first part captures the incoming fire of the OTH weapons. The second part evaluated the engagement of the OTH target based on the surviving swarm UAVs. The SSS includes functionality that disables the targeting and capabilities of UAVs that have been hit by the OTH salvo.

The SSS is shown in Figure 24 was used to conduct an additional assessment of the UAV performance factors. This data was used to build confidence in the modeling results as well as provide further evaluation of the scenario success drivers based on UAV performance factors.

1795 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

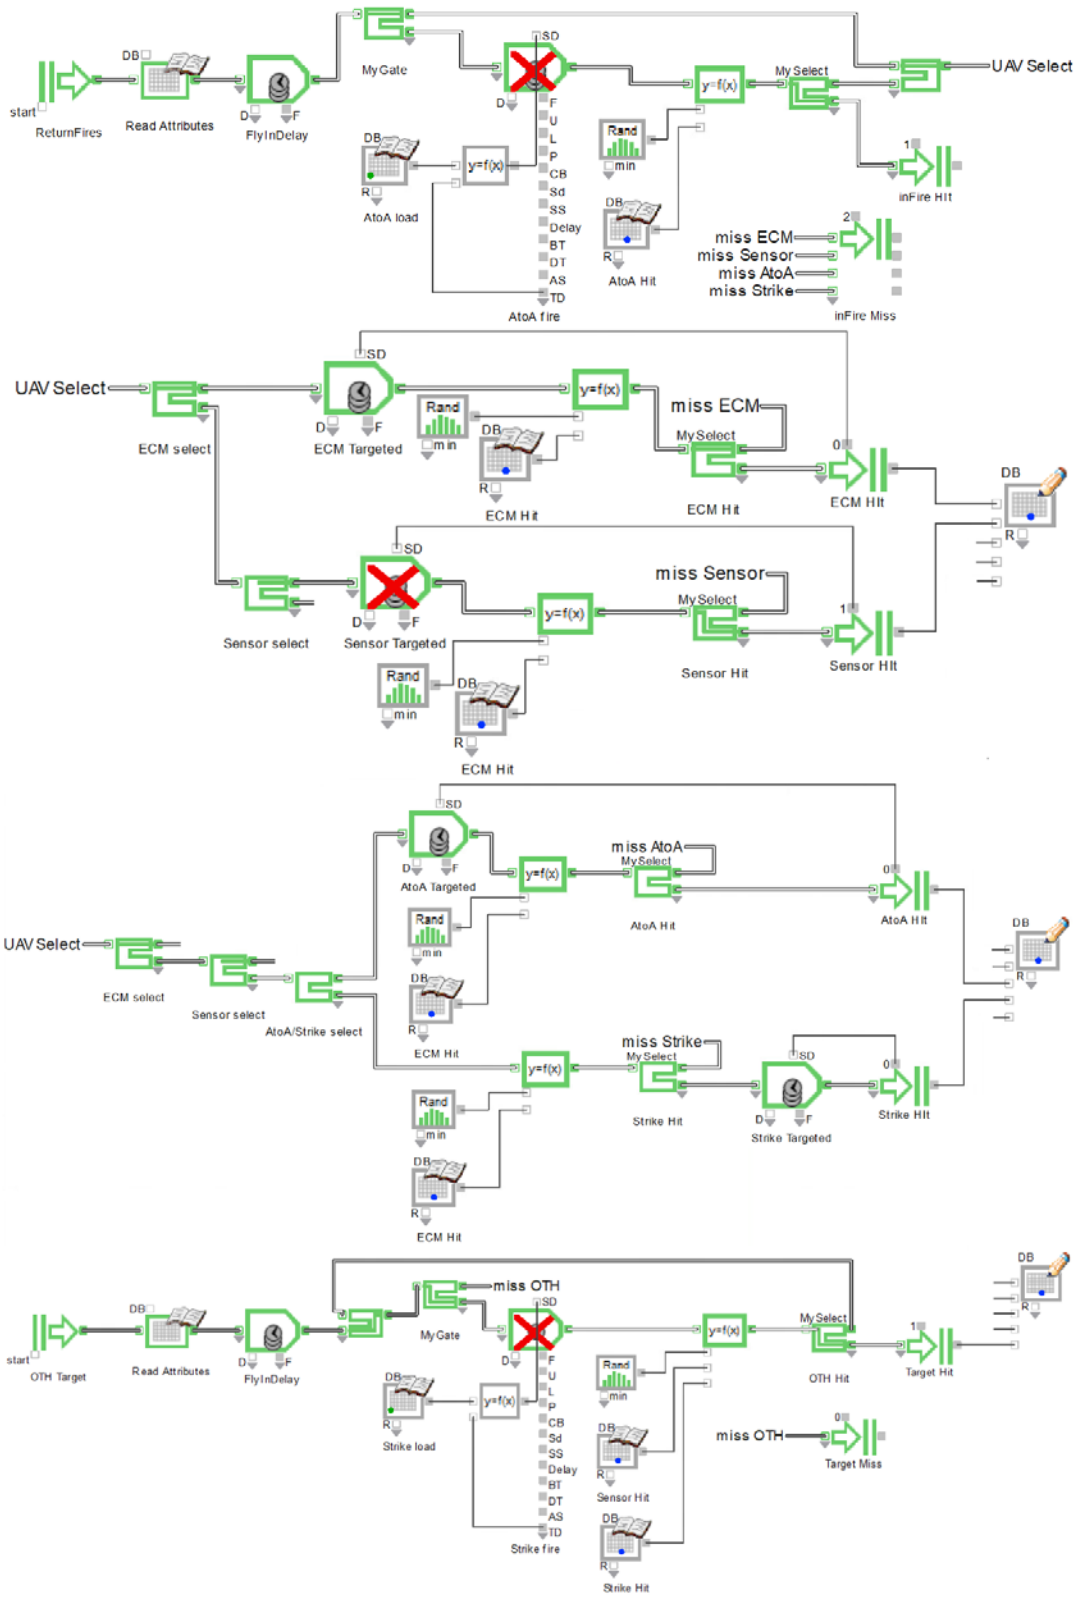

Figure 24. Swarm Strike Simulation

1796 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

When the SSS functionality matured, 20 runs of data were collected using the same performance parameters as the model data from Table 5. This data is shown in Table 10. The variance from the SSS for the $P_{Success}$ is smaller than the SSM which shows that the simulation has a more repeatable assessment of $P_{Success}$. The variance from the SSS for the P_{Hit} is larger than the SSM which shows that the model has a more repeatable assessment of P_{Hit}. The P_{Hit} variation could be due to the higher fidelity implementation of the UAV targeting in the SSS.

Table 10. Swarm Strike Simulation Output Variance

Simulation	**350 runs**	
Sample	$P_{Success}$	P_{Hit}
1	0.711	0.333
2	0.683	0.368

99% CI +/-	0.008	0.008

1797 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The run data from the variance assessment was used to compare the mission performance outcomes ($P_{Success}$ and P_{Hit}) averages using the Excel t-test function with unequal variances. The t-test data in Table 11 shows that the SSM and SSS are producing different results for the mission outcomes. This was expected, as the refinement provided by the SSS should have a significant impact on the mission outcome.

Table 11. Swarm Strike Simulation UAV Performance DOE

1798 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Now that the SSS fidelity has been assessed, the OTH mission can be analyzed. This was done through the execution of the performance DOE parameters from the modeling assessment shown in Table 6. The DOE parameters were run through the SSS with 350 executions per row. Table 12 shows both the DOE inputs and outputs for the UAV performance in the SSS.

Table 12. Swarm Strike Simulation UAV Performance DOE

P_{ECM}	P_{Sensor}	$P_{A/A}$	P_{Strike}	A/A Loadout	Strike Loadout	$P_{Success}$	P_{Hit}
0.20	0.50	0.64	0.64	1	4	0.651	0.414
0.20	0.50	0.64	0.84	4	1	0.800	0.193

The performance results from the SSS reinforce the performance analysis from the SSM. This increases the confidence that the analysis and findings from the modeling effort are useful. The DOE analysis from Minitab produced the same main effects results that were observed in the modeling analysis. These effects are shown in Figures 25 and 26.

1799 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

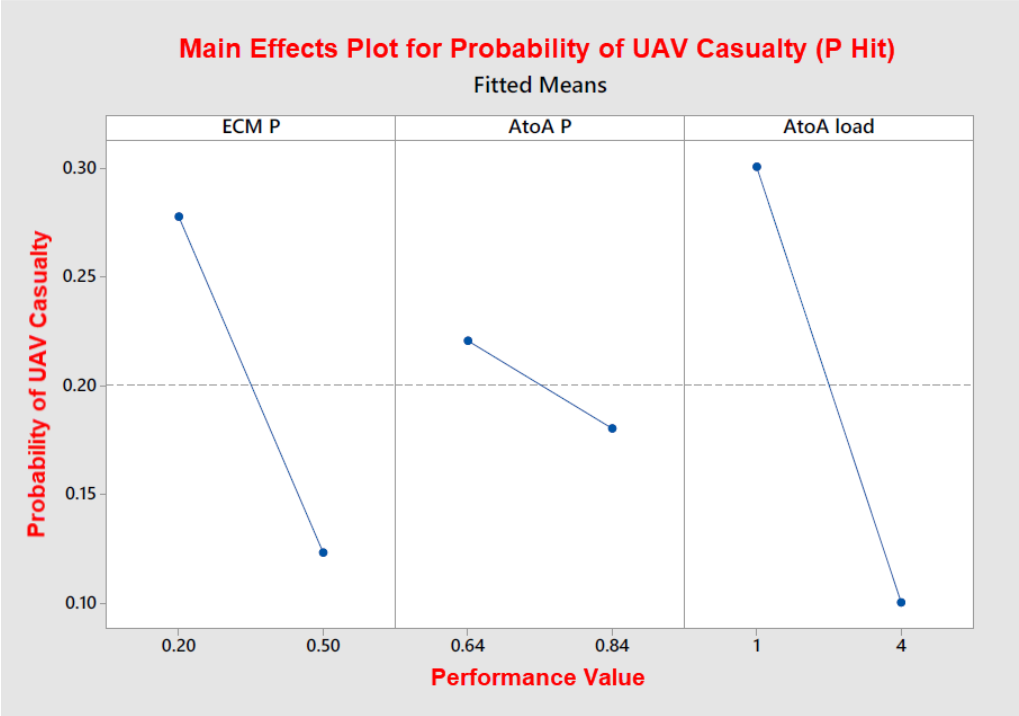

Figure 25. Swarm Strike Simulation Probability of Hit Main Effects Plot

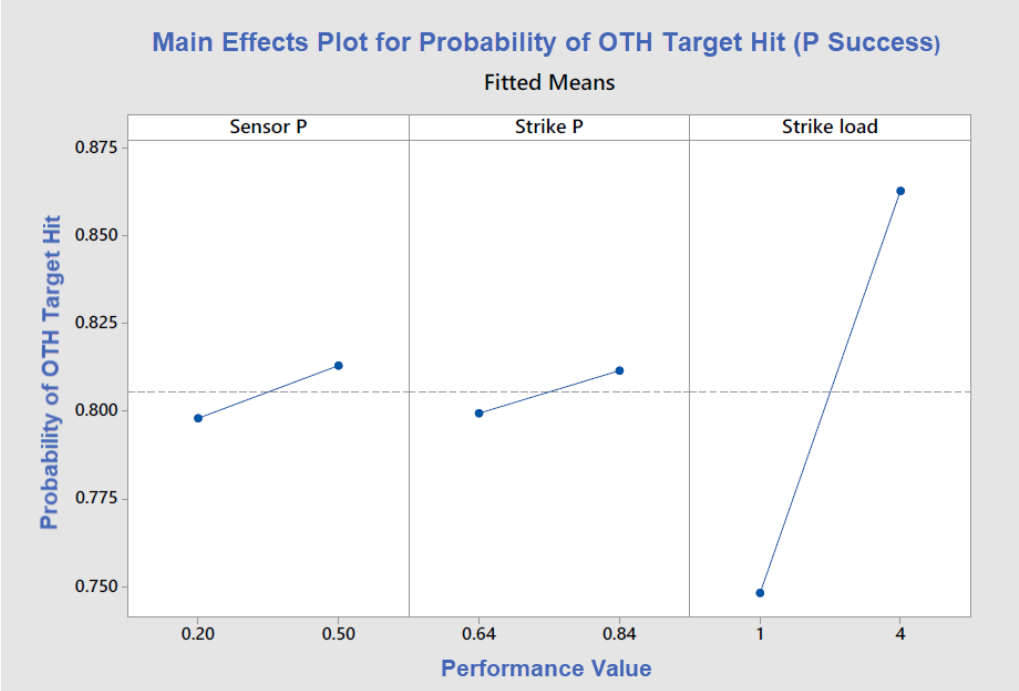

Figure 26. Swarm Strike Simulation Probability of Success Main Effects Plot

1800 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

This simulation could be utilized to further explore the UAV performance through the addition of an extended time delay for the engagements, which was not captured in this data. If the time between the release of the OTH weapons was lengthened to the point where an A/A UAV was hit, the swarm capability to intercept the next weapon would be reduced. This could result in changes to the performance driver analysis.

The M&S effort produced data that was well-matched and provided confidence that the scenario is producing believable results. It also provided the performance assessments for this project. Based on the development and assessment of the M&S tool, a usable table of swarm configurations was developed. The UAV performance factors that were identified as scenario success drivers helped identify critical UAV capabilities within the swarm. The data and analyses developed can be used to help inform the development of a BREM swarm capability.

D. COST ANALYSIS

With the move towards the usage of UAVs for combat, it is important to look at the cost implications. In a 2012 study, the average unit cost for a Lockheed Martin F-22 Raptor was approximately $186M (Boyle 2012). In addition, the average yearly cost for operations and support for each aircraft was approximately $11.5M with each flight hour costing the military $11.5K (Boyle 2012). Likewise, the Lockheed Martin F-35 Lighting II has an estimated unit cost of $91M with an average yearly operations and support cost of $5M per aircraft (Boyle 2012); current estimates expect the Lighting II's cost per flight hour to be reduced to $25K (McCarthy 2018). The premier electronic attack platform, the Boeing EA-18G Growler, costs an estimated $70M per unit (Defense Acquisition Management Information Retrieval 2017) with an average yearly operations and support cost per aircraft of approximately $6M; the cost to operate the Growler per flight hour is $25K (Defense Acquisition Management Information Retrieval 2017). With the high unit and operational and support costs, it is worth considering the cost-benefit of tasking UAV platforms to fulfill these critical roles.

From the same 2012 study, the unit cost for a General Atomics MQ-1C Gray Eagle was cited at $26.5M with an average yearly operations and support cost of $8M per unit,

1801 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

per year (Boyle 2012). Similarly, the General Atomics MQ-9 Reaper was reported to have a per-unit cost of $6.5M per unit with operations and support cost of $3M per unit, per year; the per flight hour cost for the Reaper is estimated at $3.25K (Boyle,2012). Likewise, the Northrop Grumman RQ-4 Global Hawk's has an average unit cost was $103M with an operations and support cost of $15.6M per unit, per year; the per flight hour cost for the Global Hawk is estimated at $31K (Boyle 2012). Table 13 summarizes unit and flight-hour costs.

Table 13. Cost Comparison of Manned and Unmanned Platforms

Mission Role	Strike/A/A				Sensor/ECM	
Platform	F-22 (M)	F-35 (M)	MQ-1C (U)	MQ-9 (U)	EA-18G (M)	RQ-4 (U)
Unit Cost ($M)	186	91	26.5	6.5	70	103
Flight Hour Cost ($K)	11.5	25	-	3.25	25	31
(M) – manned platform, (U) – unmanned platform						

A comparison of the costs of aerial vehicles shows an especially large variance between the unit cost. Both the MQ-1C Gray Eagle and MQ-9 Reaper are used specifically for combat, like the F-22 Raptor and F-35 Lightning II. The F-22 and F-35 may be equipped with an ECM system. Similarly, the MQ-1C Gray Eagle and MQ-9 Reaper have an available ECM payload (Air Force Technology n.d.). When comparing the UAVs to the manned combat vehicles, the conclusion becomes clearer. The average unit cost of the two conventional manned aircraft is $132M. Conversely, the two combat-capable UAVs average $19M per unit. The RQ-4 Global Hawk is primarily used for its reconnaissance capabilities which makes it a great selection for the sensor-enabled UAV. On a similar note, the EA-18G Growler is strictly purposed for electronic warfare, surveillance, and reconnaissance. Evaluated strictly on cost, the UAV option is less favorable. Although the RQ-4 Global Hawk exceeds the EA-18G Growler in unit cost, O&S cost, and flight-hour costs, its deployment eliminates the risk of service member casualties.

Reflecting on Chapter IV, the foundation provided by previous chapters allowed for the modeling and simulation of the OTH mission execution by the UAV swarm. The

1802 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

follow-on analyses found consensus in that OTH mission success is most affected by weapon stores (A/A and strike munitions). Also, the comparative cost analysis for manned versus unmanned platforms found the unmanned platform alternatives to be less costly, save for the ECM function, while eliminating the risk to service members that would otherwise be fulfilling platform role. Moving into Chapter V, the findings of this project will be further discussed with the contributions and potential application benefits identified. The chapter will conclude with a look towards future work that would aid in the further development of the BREM project.

1804 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

V. FINDINGS AND FUTURE WORK

A. FINDINGS

The team used a modified system engineering approach to study the operational utility of adding a swarm of UAVs for the OTH mission. The approach was based on the traditional systems engineering "vee" with a focus on the development of a CONOPs and system architecture, and modeling and simulation (M&S) analysis. The team developed the SSM and ran scenarios to conduct three sets of analyses. The analyses centered on the execution of the OTH mission and included a UAV performance analysis, a swarm size analysis, and a swarm configuration analysis.

The CONOPs development process identified specific UAV configurations for use in the swarm. The process also captured the functional description of the UAV configurations and related the performance of the respective UAV platform as a member of the swarm. The CONOPs itself described the basics of swarm configuration as it relates to executing the OTH mission. The CONOPs also began the development of the BREM swarm mission definitions and the OTH mission scenarios.

The architecting processes that followed the CONOPS development further matured the CONOPs by establishing the system of systems definitions for the BREM swarm. The team produced a series of operational and system views that identified UAV configuration data and communications needs. The architecture aided in describing the need for support assets in the execution of the BREM swarm mission.

The team conducted an M&S effort as a quantitative approach for assessing swarm success during the execution of the OTH strike scenario. The SSM, developed in Microsoft Excel, took a probabilistic approach to capture and evaluate the OTH strike scenario. The SSS used a similar approach to scenario execution but added fidelity to the weapon engagements and was developed in ExtendSim9. The scenario utilized in the M&S effort was developed using the information captured in the CONOPs. The quantitative approach of the M&S effort established performance metrics for the various UAV configurations. The effort also allowed for the capture of swarm size and configuration on OTH mission

1805 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

success. To this end, mission success was evaluated using the probability the swarm would kill the OTH target contrasted against the probability of a loss of a swarm UAV.

A DOE was developed for the UAV performance using the M&S metrics and analysis was completed using the SSM. The results from each of the DOEs were evaluated for main effects drivers. In the UAV performance modeling analysis, the strike loadout was identified as the driving parameter for the OTH hit probability. The analysis also revealed the A/A loadout to be the main driver of the probability that an incoming threat would hit a UAV. The swarm performance assessment was repeated using the SSS with comparable results.

The swarm size assessment and configuration analysis used a standard set of UAV performance values. A DOE was developed for the swarm size assessment and completed using the SSM. The analysis found the strike UAV configuration to be the critical UAV platform for the successful engagement of the OTH target. In addition, loss of the strike UAV was most detrimental to the success of the OTH strike mission. Successive runs of the SSM were completed to obtain the data used in swarm configuration analysis. The swarm configuration analysis provided the probability of an OTH kill as well as the probability of UAV loss for the various configurations. The team produced a table of recommended swarm configurations that depend on the number of red force return fire weapons. When the red force return fire loadout is known, the look-up table (contained in Table 9) shows the minimum number and type of UAV swarm that produces a high probability of success and a low probability of being hit.

The cost analysis for utilizing current UAV technology in the execution of the OTH mission showed that a swarm implementation would likely increase the cost. However, two factors could drive the decision in favor of the use of a UAV swarm for OTH missions. The first is that delivering more UAVs in more mission areas will reduce the unit cost. The second is that as the UAV technology matures with the higher demand, the cost of delivering UAVs will be reduced. These factors, in addition to the casualty risk associated with OTH mission execution, push the decision in favor of utilizing UAVs.

1806 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

B. CONTRIBUTIONS

The modified systems approach completed during this capstone project produced several contributions to the BREM system. The project developed a CONOPs and architecture for the OTH mission that can be utilized in the pursuit of enabling swarm mission capability. In addition, the usable swarm configuration could be used as a lookup table by surface ship combat systems for the execution of the BREM swarm missions. The results of the M&S effort can aid in developing further analyses to unlock new capabilities to be implemented in the OTH mission. The method, data, and tools established by this project could be leveraged to develop similar analyses of existing naval capabilities.

C. POTENTIAL BENEFITS

A practical and near-term benefit of the study will be an Excel application and ExtendSim model to support BREM development and to be used for this project's analysis as well as future analyses. The Excel application will have an interface in which the user may input information regarding the UAVs, coordinates, weaponry, and opposing forces. The application is expected to output the strategic positioning and predictive engagement strategy. The ExtendSim program is expected to mirror the results of the Excel application and provide graphs and visuals to help illustrate.

The results of the project's analysis will provide recommendations and lessons-learned for implementing the addition of UAVs into the BREM automated mission planning decision aid. The M&S of a variety of UAV combinations and configurations for OTH missions will provide an understanding of the operational utility of UAVs for this mission domain. The analysis results will inform the stakeholders of the benefits of integrating the UAVs to the existing BREM gaming system. The stakeholders may also leverage the project towards further development of, and insight into, the BREM functionality as well as UAV capability.

UAV system developers at the forefront of the BREM project will benefit greatly from the project. The results of this study will support the autonomous decision-making component of BREM by adding the potential operational utility of UAVs to the OTH mission. The objective of BREM is consistently to stay in the optimal battle condition of

1807 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the matrix, leading to the highest probability of battle success. With the addition of UAV capabilities and strategies, the BREM will have the potential to achieve even more significant improvements in battle-readiness for OTH missions.

D. FUTURE WORK

The team recommends the swarm size and configuration modeling analysis be repeated using real-world data for UAV effectiveness and reliability. For a baseline, the UAV probabilities could be given F/A-18 performance metrics for similar missions as it is equipped with a sensor package that is similar in concept to the sensor-enabled UAV. In addition, the F/A-18 also features an escort jamming capability that matches the ECM UAV functionality. Lastly, the F/A-18 load outs could be leveraged for the A/A and strike mission package probabilities. By using the F/A-18 data, a better-informed analysis could be completed for the mission effectiveness of the BREM swarm UAVs. The use of measured or predicted values for known UAV reliability could also increase the fidelity of the modeling analysis.

The team also recommends the OTH mission, as completed by manned platforms, should be analyzed to establish a comparative baseline. The data provided by the baseline analysis would allow for a comparative analysis between manned and unmanned assets. In addition, an analysis of manned and unmanned platforms may yield a higher mission probability than either platform on its own.

Further work could be directed towards evaluating the impact of changing the UAV targeting priority during the execution of the OTH scenario. For instance, the ECM and sensor-enabled UAVs could effectively remain outside the OTH engagement range if the ECM UAV supported the swarm as a stand-off jammer with the sensor-enabled UAV acting as a loitering sensor. Removing two UAVs from the engagement area would concentrate on inbound threats, which may increase the probability of successful interception by the A/A weapons. The resulting changes to the OTH targeting methodology would likely necessitate the iteration of the UAV performance drivers and swarm size analyses.

1808 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Another area of development would be enhancing the OTH scenario to reflect a dynamic environment. The addition of swarm UAV countermeasures, environmental factors, and OTH target capabilities would add a layer of fidelity to the SSM. The inclusion of swarm countermeasures would further enhance UAV survivability. Environmental factors affecting UAV and weapon performance would provide insight into optimal swarm configurations for varying environmental conditions of real-world scenarios. Predicting and acknowledging the capabilities of the OTH target are vital to reflect the complex environment accurately in which the strike weapons must operate. Each of these factors necessitates iteration of the UAV performance drivers and swarm size analyses to enable a more versatile swarm configuration.

Further engagement cost analysis would prove beneficial. Dependent on the acceptable level of risk, it would be advantageous to know which UAV configuration yields the greatest probability of success at the lowest cost. This information would provide engagement decision makers with the best cost-benefit analysis. In turn, this would support the allocation of defense spending towards the areas that have the greatest impact on OTH engagement success probability.

13. ABSTRACT (maximum 200 words)

This capstone project studied the mission utility of using unmanned aerial vehicle (UAV) systems to accomplish the over-the-horizon mission by modeling a variety of UAV capabilities and evaluating their contribution. An Excel probabilistic model of the mission was created to determine the optimized weapon loadout and swarm configuration, which assumed the electronic countermeasures (ECM) UAV to have the highest probability of enemy engagement due to its lead formation position and large radar signature. An ExtendSim simulation added a time element to the study. Both the model and simulation revealed that a maximum air-to-air and strike weapon loadout, which is four weapons for each role, yields the highest probability of success at the lowest probability of a UAV casualty. A maximum air-to-air and strike loadout was found to produce success and UAV casualty probabilities of 98 and 3 percent, respectively. A comparative cost analysis assessed the financial viability of substituting UAVs for manned platforms. The analysis found the unit and per-flight hour cost, for all UAV platforms except those that fulfill the ECM role, to be less than the cost for manned counterparts. However, the use of the ECM UAV eliminates the potential for a flight crewmember casualty.

EXECUTIVE SUMMARY

Naval Air Warfare Center, Weapons Division, China Lake, is developing an automated decision aid for over-the-horizon targeting (OTH-T) and strikes (OTH-S), called the Battle Readiness Engagement Management (BREM) system. The BREM system, which is currently in the research and development phase, is envisioned as a decision aid to military decision makers by evaluating different OTH courses of action based on game theory and artificial intelligence. The BREM project has developed a prototype OTH targeting and strike game for evaluating a wide range of challenges, actions, and outcomes based on complex "real world" conflicts.

The BREM game's initial scope includes air-launched OTH smart weapons and similar adversarial threats. The primary area of interest of this project is to expand the BREM scope to include the utilization of unmanned aerial vehicles (UAVs). The unmanned platform has the potential to redefine the battlespace by augmenting many existing capabilities, such as carrying offensive missile payloads and electronic warfare pods, as well as providing OTH sensor surveillance and defensive capabilities. Operating multiple UAVs in a swarm allows for a mix of UAVs with specialized payloads, to further shape the battlespace.

Research began with developing a concept of operations (CONOPS). The CONOPS consists of the baselined interactions, strategies, and configurations for how a system of UAV systems can provide capabilities for OTH missions. With the incorporation BREM, the goal is to achieve the highest chance of mission success while using the fewest amount of resources. To do so, inputs such as the operation scenario, available resources, and threat data feed into a decision matrix. At this point, the decision matrix serves as the brains of the system, autonomously generating an optimized plan of attack. This plan will consist of the number of UAVs required for the mission, which type will be most effective, loadout configurations for each unit, and the strategy for executing the mission.

Establishing this functionality served as a launching point for architectural analysis. The DOD Architecture Framework (DoDAF) 2.02 was utilized as a guideline for capturing

1830 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the overall architecture. The UGN team was able to capture and illustrate many factors of the OTH mission: physical assets, the interaction of external systems, the flow of functionality, internal systems, internal communications, and functional allocation. The in-depth knowledge acquired from these DoDAF models fueled the development of modeling and simulation parameters.

The goal of the modeling and simulation effort was to quantify the effectiveness of various factors of an OTH strike mission. Modeling focused on two critical probabilities: the probability of striking the OTH target and the probability of a swarm UAV being hit. Both are driven by factors such as UAV selection, UAV performance, and enemy proficiency. Simulation enabled the UGN team to reinforce the data collected with modeling. The same performance parameters were used, but simulation provided a better representation of a live combat scenario (i.e., not targeting downed targets). Through modeling and simulation, the strike UAV was found to be the critical UAV platform for the successful engagement of the OTH target. In addition, loss of the strike UAV had the most detrimental impact on the success probability of the OTH strike mission.

This UGN team is convinced the results of the modeling and simulation effort can aid in developing further analyses to unlock new capabilities to be implemented in the OTH mission. An Excel application and ExtendSim model will be the near-term deliverables provided to support BREM development. This data provides a sufficient baseline, but the UGN Team recommends the swarm size analysis be repeated using real-world probabilities for UAV effectiveness and reliability.

I. INTRODUCTION

The over-the-horizon (OTH) mission is one of the most challenging engagements for modern weapons systems. The mission engagement is driven by the complexity of data transfer of target information due to the break in the line of sight from the horizon, as well as sensor error budgets from long mission execution times. The mission is further strained by the limits of weapons loadouts and adversarial counter-tactics. The complexities of the OTH mission area present a decision space that can benefit from automated decision aids to support human warfighting decision makers. Automated decision aids could support the selection of sensors for target data support and the selection of available weapons.

The Naval Air Warfare Center, Weapons Division, China Lake, is developing an automated decision aid for OTH missions, called the Battle Readiness Engagement Management (BREM) system (Nagy 2019). The BREM system, which is currently in the research and development phase, is envisioned as a decision aid to military decision makers by developing and evaluating different OTH courses of action. The BREM system incorporates game theory and machine learning to develop OTH courses of action and evaluate these options based on expected consequences and predicted adversarial responses (Johnson 2019). The BREM system will develop battle plans to determine when and how to use kinetic and non-kinetic weapons to support various OTH targeting and strike missions. The BREM program is using an incremental learning approach to ensure readiness in the successful execution and management of missions involving complex planning. This learning approach includes de-escalation tactics while also recommending the selection of available weapons, communications, and sensors that yield the highest likelihood of mission success. The BREM system is focused on leveraging the increased readiness provided by the system to reduce casualties and maximize results.

The BREM system's initial scope includes air-launched smart OTH weapons and similar adversarial threats. One area of interest is an expansion of the BREM system to include the contribution of unmanned aerial vehicles (UAVs) to the OTH mission. This capstone project studied the mission utility of adding UAVs to the OTH mission by modeling a variety of UAV capabilities in conjunction with the BREM system. The study

1832 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

looked at the use of different types of UAVs (missile payload, electronic countermeasure [ECM] pod, sensor, defensive, etc.) in different configurations and combinations (single UAVs to swarms of UAVs) using modeling and simulation to evaluate probabilities of mission success. The study supports the incorporation of UAVs as contributors to OTH mission operations into the BREM system decision space.

A recent NPS systems engineering student team developed an operational scenario and conceptual design architecture for the BREM system with a focus on weapons selection and determining salvo size and weapons trajectories (Fava et al. 2019). The student team compared the use of a future BREM system in an operational scenario to a purely human decision process. This showed how a BREM system may be incorporated into future OTH missions and how the automated decision-making capability could be leveraged across platforms to enable autonomous OTH multi-mission engagement.

This capstone project built upon the foundation laid by the previous NPS systems engineering student study (Fava et al. 2019) to model and analyze the contribution of UAVs to the OTH mission domain. The goal of this project is to provide an understanding of the operational utility of adding UAV capabilities to OTH missions. In addition, this capstone project aims to support the implementation of the UAV OTH decision space within the BREM gaming system. The capstone project team has conducted a systems engineering modeling and simulation analysis to capture the functions, architecture, data flow, event sequences, and concepts of operation used in various combinations and configurations of UAVs to assess the factors involved in improving OTH missions.

A. PROBLEM STATEMENT

The OTH mission presents a complex and stressing military decision domain for tactical decision makers. The complexity of this mission arises from incomplete and often inaccurate knowledge of the battlespace; the speed, kinematics, autonomy and destructive capabilities of modern strike weapons; unknown aspects of the adversary; unpredictable consequences of tactical decisions; adversarial means of obfuscation, countermeasures, and counterstrikes; and the general complexities of the operational environment including the beyond-line-of-sight distances. The complexities of the OTH mission area present a

1833 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

decision space that can benefit from automated decision aids to support human warfighting decision makers. The Navy is developing the BREM system as an automated OTH decision aid; however, BREM is not complete and currently lacks the consideration of naval UAV assets as contributors to the OTH mission space. This capstone study addresses this need by analyzing the potential contributions of UAVs to the OTH mission and supporting the implementation of adding this knowledge to the BREM decision aid system.

B. CAPSTONE PROJECT OBJECTIVES

The primary objective of this capstone project was to study the mission utility of adding UAVs to the OTH mission by modeling a variety of UAV capabilities in conjunction with the BREM game system. The study looked at the use of different types of UAVs (such as those with payload, ECM, sensor, and air-to-air defensive capabilities) in various configurations and combinations (single UAVs to swarms of UAVs) using modeling and simulation to evaluate probabilities of mission success. An additional objective of the study was to support the incorporation of UAVs into the BREM mission planning game system.

C. SCOPE, ASSUMPTIONS, AND CONSTRAINTS

The focus of this project was the application of a systems engineering analysis process to study the potential contribution of UAV capabilities for the OTH mission. Therefore, the scope of the project included:

- naval UAV assets
- OTH targeting and strike missions
- BREM as a decision aid under development
- modeling and simulation methods of performance assessments

The assumptions and constraints for this project were generated based upon the need for defining some of the mission parameter unknowns. These assumptions were used

1834 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

to reduce the complexity and bound mission parameters for the probabilistic analysis of systems performance. The assumptions are as follows:

- The OTH mission is not dependent on a single surface ship type for the OTH swarm mission execution
- OTH targets have a maximum return fire capability of four rounds.
- The performance of the return fire threats will be susceptible to electronic countermeasures ECM.
- The target tracking of the return fire threats is radar-based.
- The minimum UAV selection for the swarm engagement includes at least one strike UAV.

D. METHODOLOGY

The team developed a tailored system engineering analysis approach, as shown in Figure 1. As with a traditional "Vee" systems engineering process, definition and decomposition occurred as the project traversed down the left side, and testing and integration occurred as the project continued up the right side. This approach began with concept development, which included the development of a concept of operation (CONOPS). The CONOPS was then used to transition into the architectural analysis and the development of functional and architectural models based on the Department of Defense Architecture Framework (DoDAF). After completing the functional/architectural analysis, these models were used to create parameters for a mission execution simulation. After simulation development, the team evaluated the model evaluation and studied the analysis results.

1835 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

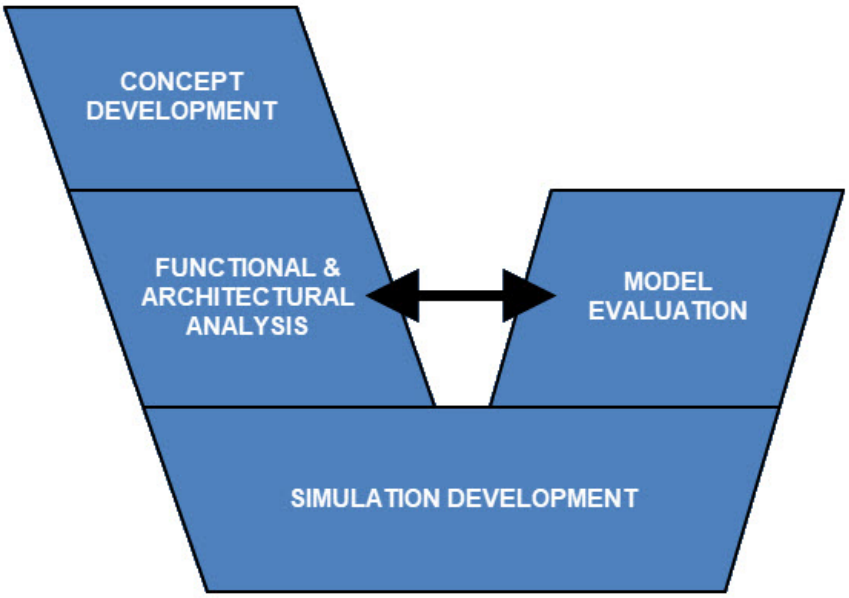

Figure 1. Modified Systems "V"

E. TEAM ORGANIZATION

Each team member had an identified set of roles and responsibilities that enabled the successful completion of the project. The fulfilled responsibilities are identified as follows:

Team Lead—Rod Harris

- Responsibilities: setup meeting agendas, kept meetings on track, kept workload distributed, kept team members accountable for attendance and deliverables

Lead Editor—Joshua Taylor

- Responsibilities: reviewed and submitted all deliverables, supported tracking, review, and accountability of deliverables

Systems Development Lead—Chris Kleparek

- Responsibilities: Ensured the systems engineering processes were being utilized, posted meeting minutes and actions to the Sakai team resource site, tracked-and-closed actions

1836 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Modeling and Simulation Lead—Chadwick Boyd

- Responsibilities: strategically organized architecture, modeling, and simulation solutions to ensure project objectives were achieved

Specialists, Analysts—All

- Responsibilities: remained accountable and diligent for completing tasking

F. CAPSTONE REPORT ORGANIZATION

The purpose of this report is to capture the analysis and results of the project execution. The report follows the systems engineering approach previously described. Chapter II presents the team's OTH UAV concept of operations (CONOPS). Chapter III contains the team's architectural analysis that describes the OTH UAV system of systems and functional architecture. Chapter IV describes the team's modeling and simulation analysis and performance analysis results. Chapter V reflects on the report's findings, identifies contributions, highlights potential benefits, and outlines future work to be undertaken by successive efforts.

Reflecting on Chapter I, the problem and scope of the project was defined and the underlying assumptions and constraints were identified to aid the reader in realizing the goal for this project. In addition, the team organization, project methodology, and report organization were introduced to provide the reader with a better understanding of the team element undertaking this project. Moving into Chapter II, the CONOPS, types of UAVs, operational scenarios, and battle strategies will be discussed to provide the foundation for the modeling and simulation effort.

1837 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

II. CONCEPT OF OPERATIONS FOR UNMANNED AERIAL VEHICLES TO SUPPORT OVER-THE-HORIZON MISSIONS

The team developed a concept of operations (CONOPS) as a basis for developing a model and simulation (M&S) of UAV operations to support the OTH mission. The CONOPS details the operation of UAV systems of systems (SoS) in conjunction with the BREM decision aid system during an over-the-horizon targeting (OTH-T) and strike (OTH-S) mission. The CONOPS consists of the baselined interactions, strategies, and configurations for how a UAV SoS can provide capabilities for OTH missions. Establishing a CONOPS serves as a launching point for more in-depth content of the project: it provides the information necessary to develop architectural DoDAF models (Chapter III) and serves as the basis for parameter selection and M&S development (Chapter IV and V).

A. CONCEPT OF OPERATIONS DESCRIPTION

This CONOPS provides details of how UAVs could operate in conjunction with BREM decision aid system to improve OTH missions. Figure 2 illustrates this operational concept. Adding blue force UAVs as a SoS to the OTH mission can improve situational awareness, threat targeting, communication, countermeasures, and both defensive and offensive OTH actions. The role of the BREM system, as a decision aid, is to determine how a UAV SoS can best support the gathering of threat data and battle strategies (such as formations, loadout selection, resource management) to improve OTH missions. This CONOPS focuses on the successful utilization of blue force assets to neutralize a present threat, whether engaged in an offensive or defensive combat scenario.

1838 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

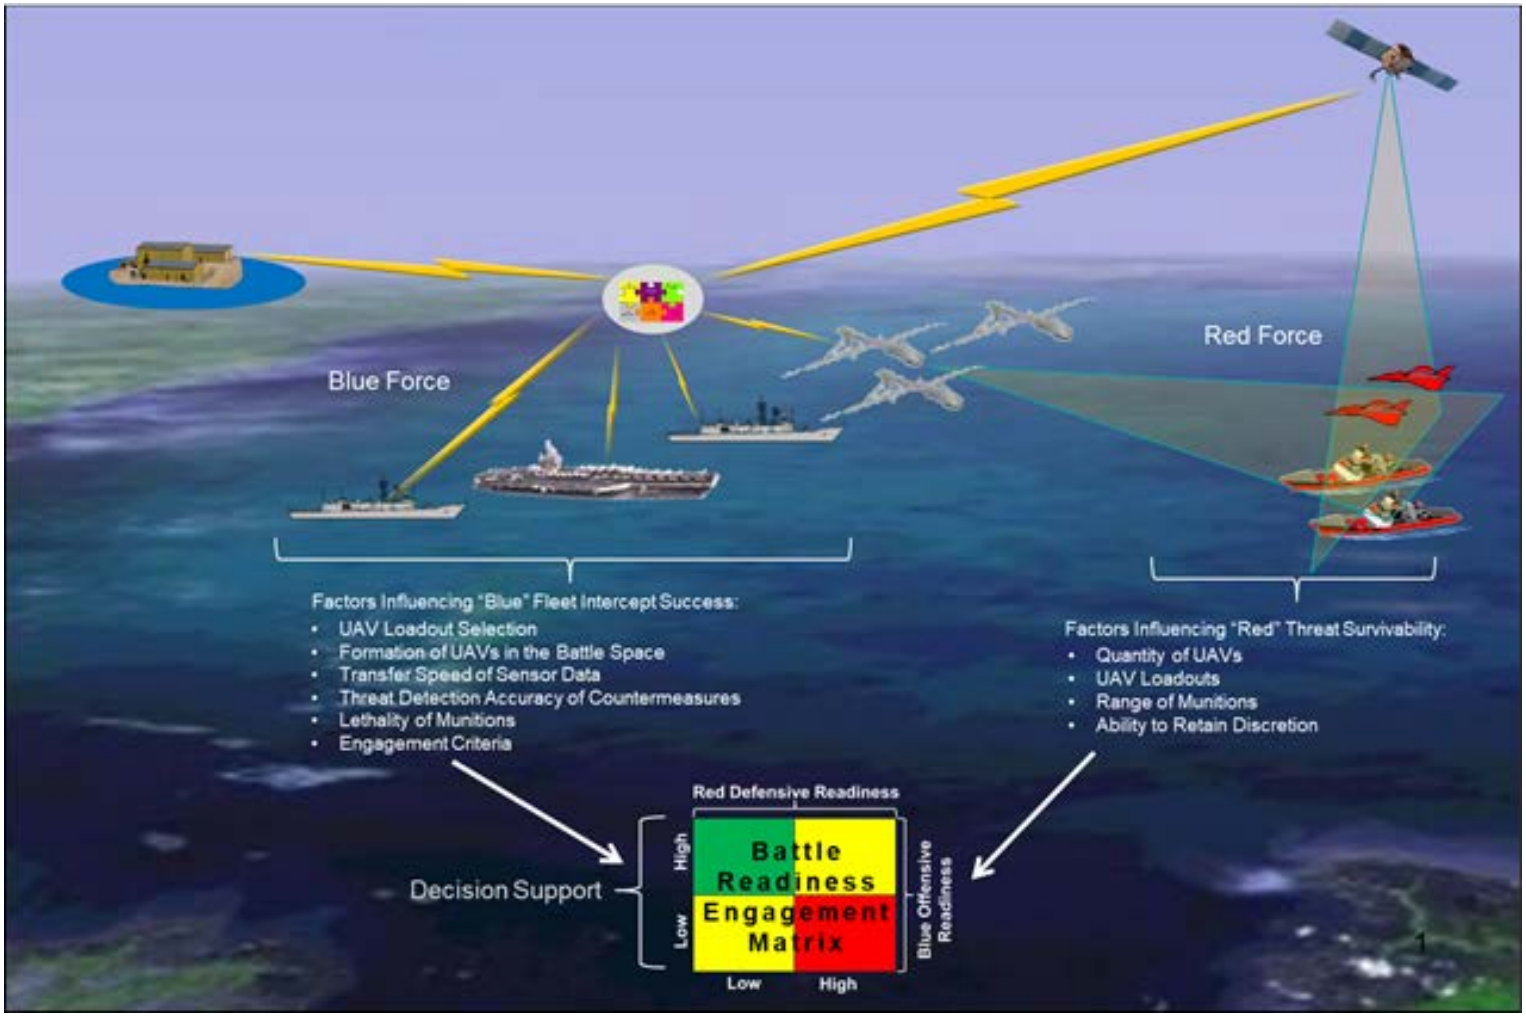

Figure 2. OV-1: Operational Concept for BREM and UAV SoS for OTH Missions

1839 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The CONOPS details the structure of the UAV system of systems (SoS) and its relationship to the BREM system. The CONOPS is based on information that is leveraged from Department of Defense weapon system experience and research detailing stochastic game theory, battle simulations, capabilities-based planning, and systems development. The CONOPS considers current capabilities for UAVs, radar, communications, and weapon systems.

As illustrated in Figure 2, the OTH mission domain includes blue force assets such as a naval strike group that can perform strike missions against a red force. The red force may defend itself with countermeasures and warfare strikes such as missile launches from ships and aircraft. The BREM system is shown in the figure as a colored cube representing this decision aid system that develops OTH courses of action (COA) and also evaluates the risk level of each COA—as green, yellow, or red. This CONOPS describes the use of the BREM system to determine how a UAV SoS could best support the blue force's OTH mission. The BREM tool would be used to deliver an estimation of the probability of success of COAs involving the engagement conditions of a given scenario. The engagement conditions include the following: types and quantity of blue force UAVs present, types and quantity of red force UAVs present, radar detection rates, ECM success rates, missile neutralization rates, and missile intercept rates.

The BREM is a tool used to illustrate this desired readiness condition. Mission success, represented as a green condition, is achievable through the informed use of available resources. Suggestions regarding resource allocation will aid decision makers in determining the actions required to maximize the probability of mission success while minimizing friendly casualties. Figure 3 depicts a high-level flow chart of BREM functionality. The system will take the mission scenario, analyze current resources and threat data (such as quantity, weaponry, vulnerabilities), and generate an optimal plan of attack. This plan will consist of the number of UAVs required for the mission, which type will be most effective, loadout configurations for each unit, and the strategy for executing the mission. This strategy will consist of communication, UAV coordination, reporting of sensor data, firing of weaponry, deployment of countermeasures, and all other functions required for mission success.

1840 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

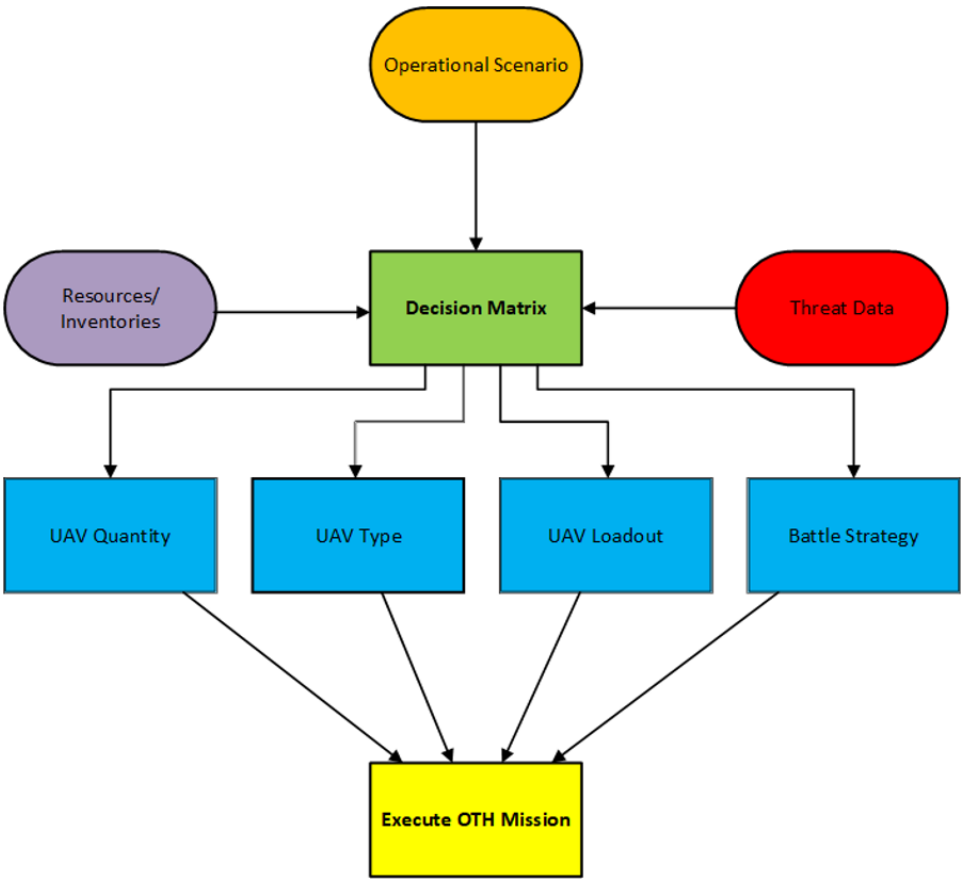

Figure 3. Operational Flow Chart

B. TYPES OF UNMANNED AERIAL VEHICLES

1. Sensor-Enabled Unmanned Aerial Vehicles

Sensor-enabled UAVs support the target and threat detection and tracking data needs for the blue force. This type of UAV supports the OTH-T mission. This information may then be used to support UAVs capable of electronic countermeasures (ECM), air-to-air (A/A) strikes, or air to ground target strikes. The sensor-enabled UAVs improve target and threat data fidelity and provide data used for battle state assessments.

2. Air-to-Air Defense Unmanned Aerial Vehicles

Equipped with antiballistic missiles, A/A defense UAVs are capable of countering incoming missiles. These UAVs are responsible for the completion of the inbound missile

1841 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

target OTH-S missions. The capability to combat incoming threats reduces the probability of damage to a UAV in the swarm and increases the likelihood of mission success.

3. Strike Unmanned Aerial Vehicles

Strike enabled UAVs are capable of engaging and neutralizing enemy targets. These UAVs support the offensive attack portion of the OTH mission. This type of UAV's probability of kill success contributes directly to the overall OTH mission success.

4. Electronic Countermeasures Unmanned Aerial Vehicles

UAVs equipped with ECM are capable of jamming the electronics of enemy threats, thereby reducing the red force's probability of successful attacks against the blue force. ECM UAVs target the red force's radar homing systems. Effective use of ECM UAVs will reduce the likelihood of damage to the blue forces and will increase the blue force's probability of OTH mission success.

C. OPERATIONAL SCENARIOS

1. Unmanned Aerial Vehicle Strike Mission

The OTH strike mission occurs when an OTH target is identified. During this event, the user-supplied target location and identification will be used by the BREM decision aid system to assess the number of assets to deploy to meet and predicted probability of success. In the event that a strike UAV is selected to support this mission, the strike UAV must acquire, track and engage the target. The engagement will be consummated with a missile deployment. Mission success will depend on the strike UAV probability of survival as well as the probability of a successful missile intercept by the red force.

2. Unmanned Aerial Vehicle Sensor Mission

The surveillance mission requires a percentage of radar coverage for a specified area based upon the user inputs. User-supplied radar capabilities are used by the BREM decision support system to generate the number of sensor-enabled UAVs required to maintain the desired domain coverage. The sensor-enabled UAV mission success will be dependent on the radar quality of sensor-enabled UAVs in support of the OTH target

1842 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

acquisition and track. The OTH target track data is sent to the OTH strike UAV to improve its probability of missile intercept success.

3. Unmanned Aerial Vehicle Missile Intercept Mission

The OTH missile intercept mission requires allocation of an intercept missile loadout based on the user assessment of the OTH target's return fire salvo size. This mission occurs during an inbound missile threat. During this event, the A/A UAVs must launch missiles to intercept the enemy missile. Significant factors influencing the success of this type of mission is the number of inbound missiles, the number of A/A UAVs, the velocity of an inbound missile, distance from an inbound missile, detection distance, target acquisition time, missile inventory, and missile intercept rate. The mission success will be assessed as a probability of intercepting inbound missiles.

4. Unmanned Aerial Vehicle Electronic Countermeasure Mission

The ECM mission requires a specific jamming energy output based on user input regarding the OTH target's return fire capability. The jamming performance factors include distance and angle to incoming threats, as well as, the ECM UAV position in relation to the target of the inbound threat. The ECM UAV mission success improves the UAV survivability by decrementing the intercept performance of inbound threat missiles.

5. Over-the-Horizon Unmanned Aerial Vehicle Target Mission

The OTH UAV target mission occurs when there is in inbound non-weaponized UAV threat. An example of this type of mission would be an enemy UAV equipped with cameras dedicated to retrieving intelligence. During this type of mission, strike UAVs must be employed to neutralize the enemy threat. Major factors influencing the success of this type of mission are the number of strike UAVs, enemy UAV velocity, missile kill-rate, missile inventory, missile velocity, and distance from an inbound missile.

6. Over-the-Horizon Unmanned Aerial Vehicle Swarm Mission

The UAV swarm mission relies on the efforts of each type of UAV in the SoS: sensor-enabled, air-to-air, strike, and ECM. The swarm mission simulates two opposing

1843 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

swarms of UAVs, and mission success is defined by the complete neutralization of the enemy UAVs. During this mission, blue force UAVs must defend their team from inbound missiles and attack the opposing force. This mission is composed of independent OTH Missile Intercept Missions and OTH UAV Target Missions. In addition, ECM UAVs are employed to help defend the blue force by reducing the blue force casualty rate during the engagement with the red force.

7. Communications

a. Ship-to-Ship Communications

The firing ship can receive data from support ships that include incoming threat data. The threat data covers the target states, such as position (altitude and range), velocity, and target type (such as maneuvering or sea skimming). The firing ship can also send and receive data about BREM states. The BREM data will be used to support weapons selection decisions.

b. Sensor-Enabled Unmanned Aerial Vehicle-to-Ship Communications

The firing ship can receive data from support sensors that include incoming threat data. The threat data covers the target states, such as position (altitude and range), velocity, and target type (such as maneuvering or sea skimming). Sensors will also communicate environmental data for mission support.

c. Ship-to-Unmanned Aerial Vehicle Communications

The firing ship can send data to the UAVs that include incoming threat data. The threat data covers the target states such as position (altitude and range), velocity, and target type (such as maneuvering or sea-skimming) as well as environmental data such as the presence of radar jamming.

d. Unmanned Aerial Vehicle-to-Ship Communications

The UAV released for intercept engagement will communicate the status of target acquisition, target tracking, and target kill to the firing ship.

1844 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

e. UAV-to-UAV Communications

In a swarm UAV engagement, the UAVs will communicate the status of target acquisition and target track to the other UAVs. The UAVs may also transmit threat data required for target tracking.

D. MISSION BREAKDOWN

The BREM OTH scenario is a battle group mission. It includes the identification and tracking of an incoming threat or OTH target as well as the identification of the likely target. The nominal scenario starts with sensor support systems, shipboard or external, picking up a likely threat or OTH target. The threat/target information is delivered to the battle group, where the threat/target is identified as the OTH target. At this point, a target track is established using the available sensor. The sensors may be down-selected based on expected intercept complexity. The down select option allows the sensor resource to be reallocated to other tasks or shut down to prevent overuse. Once the track/position is established, target data is sent to the battle group. Based on the target data, the firing ship is selected from within the battle group. The firing ship then determines which UAV or UAV group to use for the intercept engagement. After UAVs are released, the continuation of UAV support with target state data is determined and supported if needed. The sensor systems continue to track the engagement. If the intercept/OTH mission fails, the scenario iterates until the threat is neutralized.

E. BATTLE STRATEGIES

Once the threat has been identified using a ship's radar sensing system, the BREM program selects the optimal ship to launch the unique UAV or UAV swarm with the highest probability of destroying the target. Unique UAVs are on board each vessel with different weapon selections, flight characteristics, and missile inventory. It is up to the BREM program to leverage the ship's position with the UAV information to defend against or attack the enemy. This program must also consider swarm engagement approaches and future engagements in the battle theater space. Table 1 lists types of BREM input and output, and scenario manager functions.

1845 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 1. BREM Input, Output, and Scenario Manager Functions

Input	Ship positioning (coordinates in the battle theater)
	UAV loadout (quantity for each variety on each ship, UAV weapon inventory)
	Remaining missions (number of probable future engagements
	Ship sensor data (number of threats, threat positions)
	UAV sensor data (number of threats, threat positions)
	Target (threat ID, trajectory, speed)
Output	UAV selection (ship selection, UAV team selection, weapon usages, lethality determination)
	Engagement decision (single UAV vs multiple, engagement success rate)
Scenario Manager Functions	User may select alternative UAVs to engage or create a new class of UAV
	Evaluate new engagement success rate under new theater space criteria

The engagement decision system utilizes three sets of decision factors (surface ship and UAV selection factors, event decision factors, and target decision factors) to develop the optimal battle strategy output.

Surface Ship and Unmanned Aerial Vehicle Selection Decision Factors

The position represents the coordinates of the ship in the battle theater. Each ship in the battle theater can launch its own set of UAVs teams at approaching threats and targets. The UAV loadout to be launched depends on the UAVs remaining on each ship. The multiple loadout values represent the remaining UAVs (of varying capabilities) available to execute battle tasks such as payload delivery, missile attacks, EW, and surveillance. The ship's UAV reserves are critical to ship and UAV selection. The remaining missions is another variable that is unique to each vessel.

The remaining missions are the expected number of future mission engagements based on the total number of missions allocated minus the number of missions executed. If

1846 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

a ship is likely to engage at least three more times in the theater space, there must be the appropriate resource allocation for each engagement. The resource allocation must account for missiles, UAVs, and UAV capabilities. The BREM program may require events such as payload drop-offs and ship-to-ship UAV transfers to maintain the optimal readiness condition. The fourth and final variable that is unique to each ship is the available sensor data. This sensor data is used to detect incoming threats and enemy UAVs. Due to each ship's unique positioning, each will encounter differing battle events.

1. Event Decision Factors

The target threat level represents the likelihood (*p)* of the threat to cause damage. This factor will be used in the UAV selection decision, and more specifically, the UAV quantity decision. Although the user of the BREM program may manipulate the target threat level, the default value will be set at 0.5. By increasing the threat level, the optimal position in the BREM will require a more significant swarm or attack force to neutralize the target. By decreasing the value below 0.5, non-violent approaches are preferred to reduce the likelihood of future casualties.

2. Target Decision Factors

Before selecting the appropriate means of engagement, the target attributes need to be identified and processed. Factors such as the position, trajectory, speed, and maneuverability of the target will be used to determine the optimal means of neutralization, counterattack, or surveillance approach. The ship and UAV selection are heavily dependent upon these factors. If an inbound threat is approaching a ship containing a UAV team or a non-weaponized UAV, the ship selection becomes critical to incepting the inbound threat. In this type of scenario, if a nearby UAV is in flight, it will be considered to intercept new threats.

Reflecting on Chapter II, the CONOPS, types of UAVS, operational scenarios, and battle strategies were discussed to provide the foundation for the modeling and simulation effort. Moving into Chapter III, the operational and system architecture will be defined to illustrate the relationships required between the swarm assets for mission execution.

1847 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

III. ARCHITECTURAL ANALYSIS OF A SYSTEM OF UNMANNED AERIAL VEHICLE SYSTEMS IN SUPPORT OF THE OVER-THE-HORIZON MISSION

The capstone team performed an architectural analysis of the UAV SoS for the OTH mission. The team developed architectural views based on the Department of Defense Architectural Framework (DoDAF) to capture both operational and system views of the UAV SoS. This analysis was performed to aid in the refinement and maturation of the CONOPS, to inform the UAV SoS swarm size performance analysis, and support the UAV modeling and simulation.

A. DEVELOPMENT OF BREM SYSTEM ARCHITECTURE

The architectural analysis for the OTH mission focused on describing the UAV SoS functions and architecture. The analysis generated a system architecture for the proposed OTH mission using model-based system engineering (MBSE) tools. The identification of internal and external system interactions resulting from the architectural analysis supports the future BREM system as well as the team's M&S analysis.

With the understanding of how the system is expected to operate, who is involved, and what are the assumptions and parameters of the system as developed in the CONOPS, the architecture analysis took a top-MBSE approach. This approach utilized the DODAF 2.02 as a guideline for capturing the overall architecture. The team selected Innoslate's model-based systems engineering software Innoslate to develop the DoDAF viewpoints. Knowledge of the system and parameters generated were input into Innoslate, which was then used to generate various views of the system to show operational and system-level interactions.

Utilization of the Innoslate tool offered various ways to depict the interaction of systems and subsystems, both internal and external, involved in the execution of the OTH mission. The DODAF was used to model the core functions of the BREM system as well as the various interactions between internal and external systems required for swarm operation. The overarching DODAF views focused on for this architecture of the system

1848 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

were the operational and systems viewpoints. We chose these viewpoints to illustrate the system-to-system operation as well as the execution and exchange of information between assets. When examining the views, we recommend approaching them from the perspective of an external, high-level user as many of the finer system-related details have yet to be considered.

The following are specific viewpoints developed and brief reasoning for selection:

- OV-1: High-Level Operational Concept Graphic—Offers the high-level graphical depiction of the system's operational concept
- OV-5a Physical Context Hierarchy—Captures the physical assets of the OTH mission
- External Systems Diagram (IDEF0)—Captures the functional decomposition of the mission environment and the interaction between external systems required for the execution of the BREM swarm mission.
- OV-5b: Operational Activity Model and sub-assembly decompositions—Defines the relationship between the external systems and the OTH mission as well as the internal relationships captured in the IDEF0 format
- OV-6c: Event Trace Description—Captures the sequence of events required for the OTH mission
- SV-1: Systems Interface Description—Identifies the internal systems associated with the OTH mission
- SV-2: Communications Network Diagram—Captures the intra-swarm communications required for the execution of the OTH mission
- SV-4a Functional Hierarchy—Captures the functional allocations for the OTH mission

The knowledge gained during the development of the diagrams that support the system architecture and design will aid the modeling and simulation development.

1849 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

B. OPERATIONAL ARCHITECTURE

The operational architecture view (OV) describes the operations of the system and the connections among the system and subsystems. The OV allows for evaluation of operational requirements, evaluation of interoperability issues, and system baseline. The decision was made to focus on the system analysis through the development of an OV-1, OV-5a Physical Context Diagram, OV-5b F1 External System Diagram and F2/F3 Sub-Functions decompositions, and the OV-6c Event Trace Diagram. These operational viewpoints are described in Table 2.

Table 2. DoDAF Operational Architecture for OTH Mission

DoDAF Operational Viewpoints Developed for the OTH UAV SoS	
OV-1: High-Level Operational Concept Graphic	Offers the high-level graphical depiction of the system's operational concept (Note—this is located in Chapter II of this report)
OV-5a Physical Context Hierarchy	Captures the physical assets of the OTH mission
External Systems Diagram (IDEF0)	Captures the functional decomposition of the mission environment and the interaction between external systems required for the execution of the BREM swarm mission
OV-5b: Operational Activity Model and sub-assembly decompositions	Defines the relationship between the external systems and the OTH mission as well as the internal relationships captured in the IDEF0 format
OV-6c: Event Trace Description	Captures the flow of the functions performed by each UAV during the mission execution

1. OV-5a: Hierarchy Diagram—Physical Context Diagram

The hierarchy diagram outlines the decomposition of the physical assets allocated to the BREM swarm mission execution. The physical hierarchy includes the system decompositions, as shown in Figure 4. The battle group contains the UAV swarm that will be responsible for mission execution. The UAV decompositions capture the asset's specific needs for each of the UAV configurations. The analysis used to develop this diagram reinforced that the system's assets are captured and allocated to operational activities, which are represented in the system's architecture views (SV).

1850 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

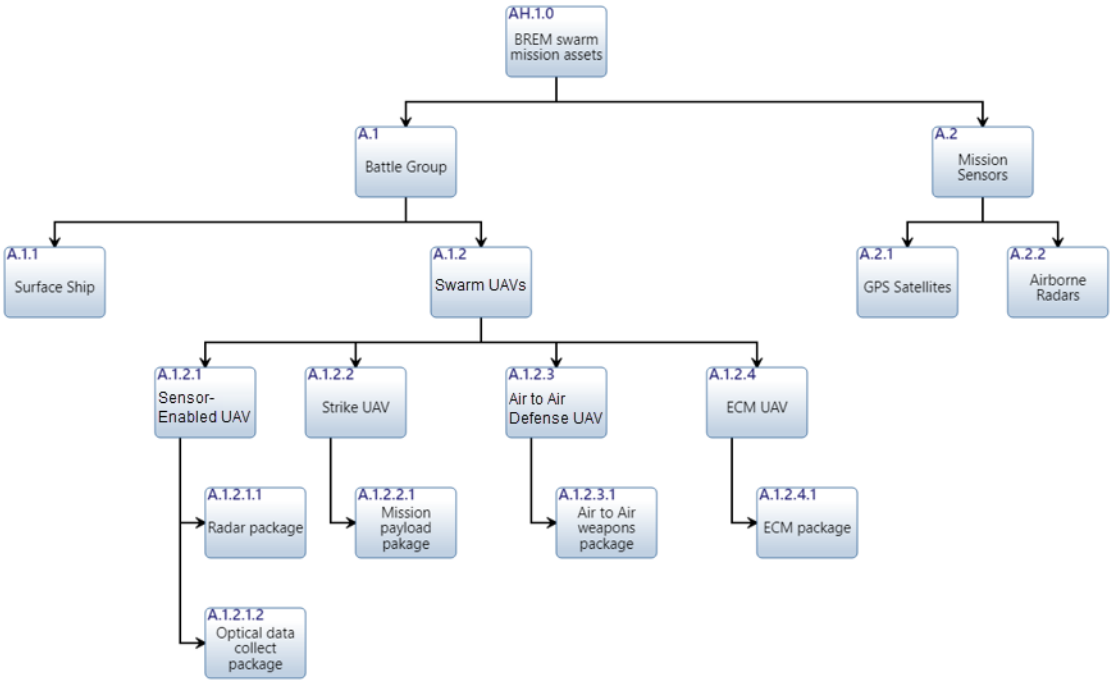

Figure 4. OV-5a: Physical Context Hierarchy

2. OV-5b: Operational Activity Diagrams

The operational activities models describe the interactions and relationships of the various system required to execute the OTH mission. These diagrams, shown in Figures 5 through 10, establish the functional architecture and identify the interactions between swarm assets and external conditions. As the team developed the architecture, each of the functional decomposition levels where labeled. The Level F-1 External System Diagram is the top of the systems architecture, the Level F-2 Execute Mission Diagram is a decomposition of the execute OTH mission function from the F-1 diagram, and Level F-3 Sub-Function decompositions of the OTH mission are captured in the remaining diagrams.

3. Level F-1 External System Diagram IDEF0

The External System Diagram (Level F-1) depicts the functions of the external systems as an SoS architecture. It also illustrates the data flow between each of the external systems. External systems include the OTH mission support systems that will not be decomposed as part of the swarm UAV architecture. The diagram aids in understanding

1851 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the cooperative nature of the external systems and the architecture of the SoS utilized in the OTH mission execution.

The external systems captured in the external systems diagram include GPS satellites, airborne tracking radars, and surface ships. These systems provide functions such as; GPS target tracking, radar target tracking, mission parameters, and launching the swarm UAVs. These functions are required for the execution of the mission but cannot be accomplished by the swarm UAVs. In this architecture, the swarm UAVs are responsible for the execution of the OTH mission functions. These functions will be decomposed in the throughout architecture. The operational relationships for these systems are shown in Figure 5.

1852 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

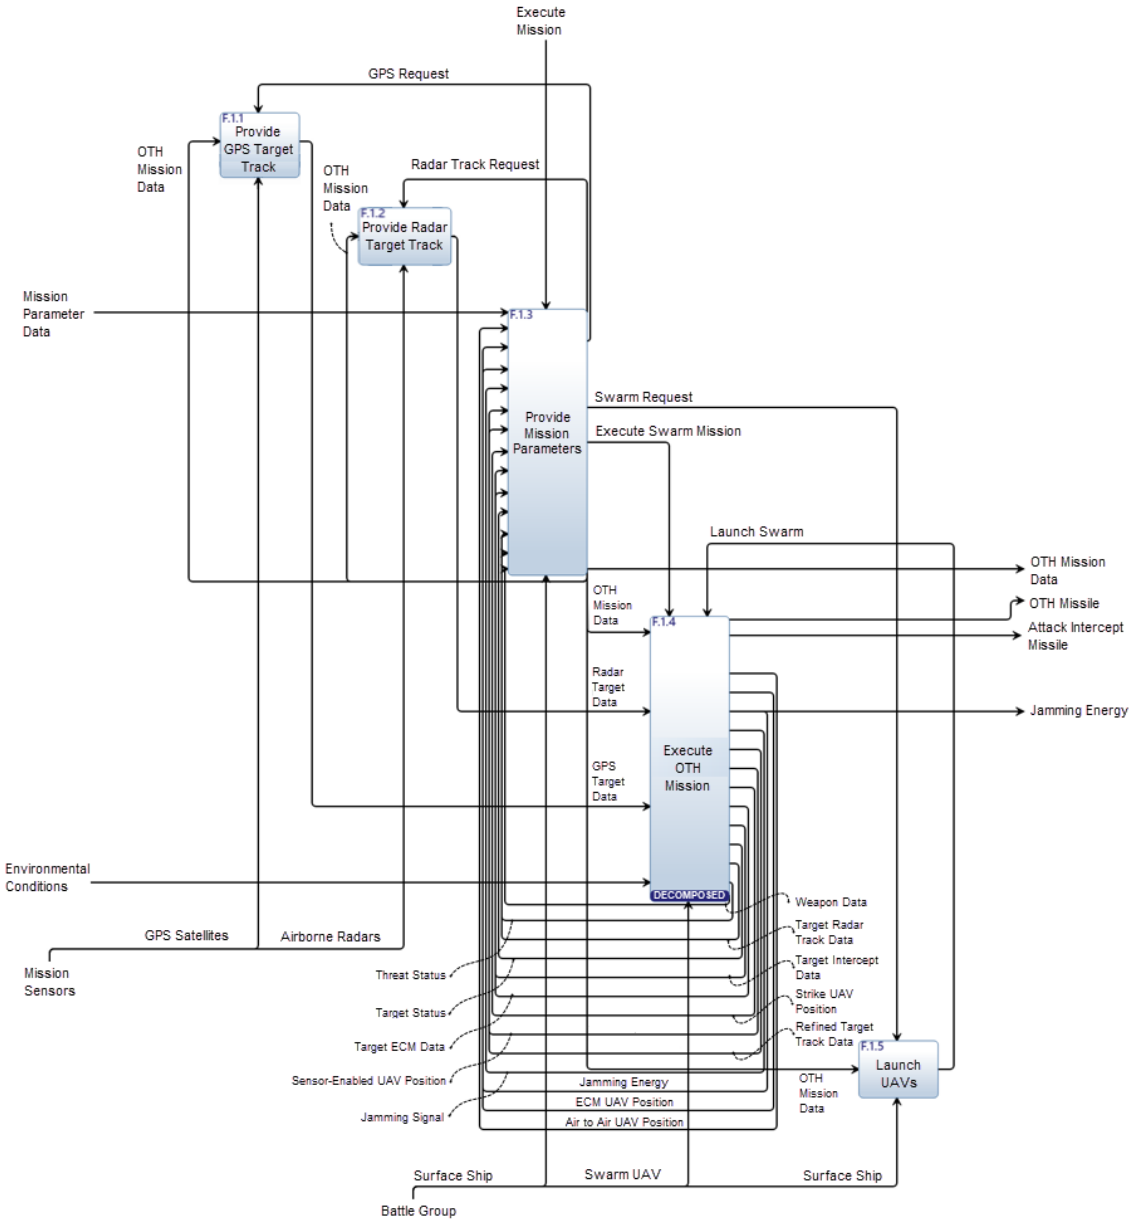

Figure 5. IDEF0: External System Diagram—External Mission Elements

1853 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

4. Level F-2 IDEF0 Sub-function Execute Mission Diagram

The interactions between the swarm assets required for mission execution are shown in Figure 6.

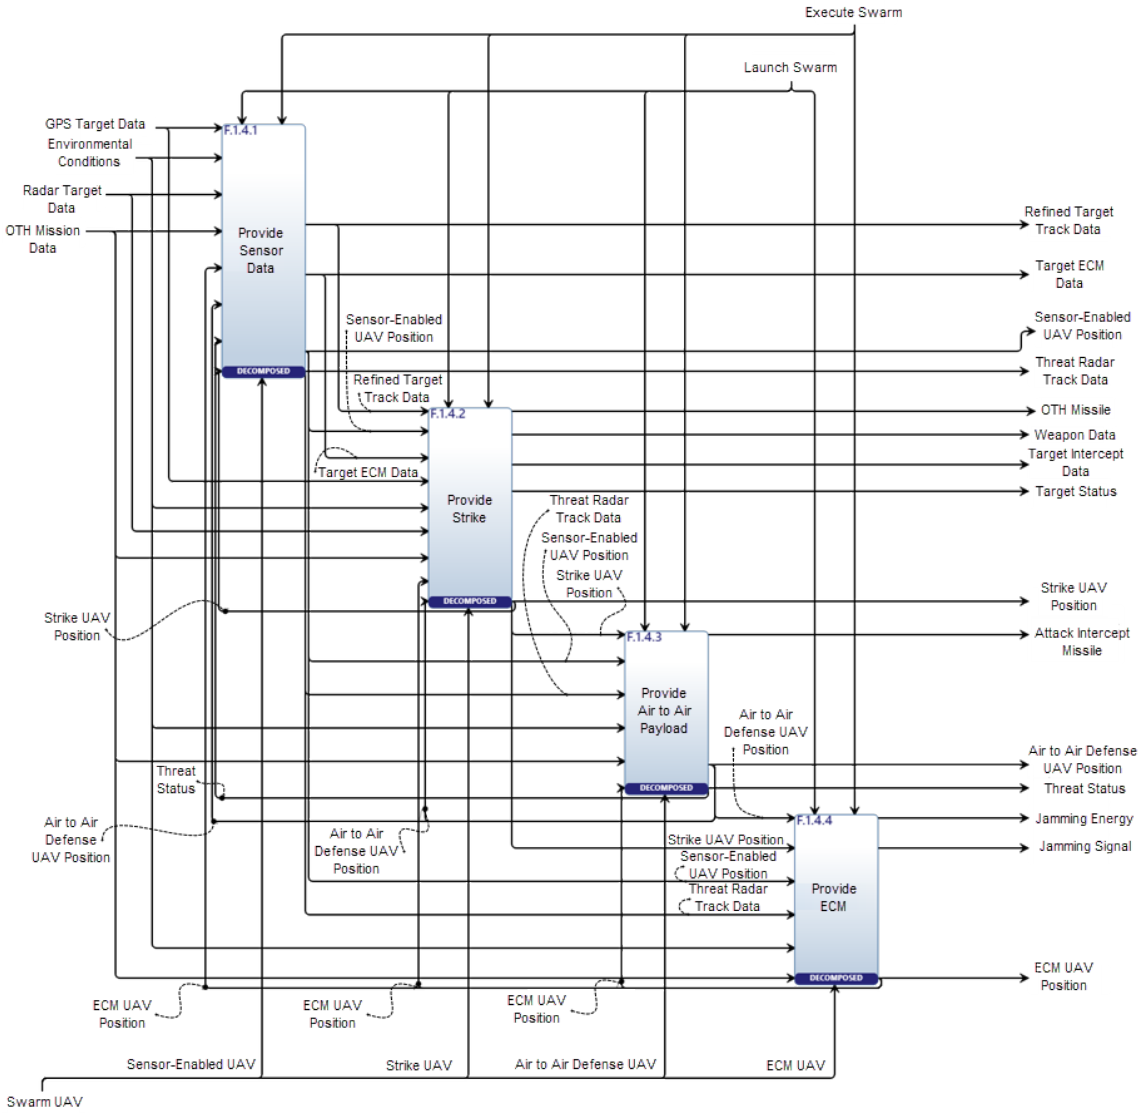

Figure 6. OV-5b: Execute Mission Context Diagram

1854 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

5. Level F-3 IDEF0 Sub-function Decompositions

The BREM Swarm Execute Mission diagram was decomposed to its sub-functions to provide a better understanding of the UAV sub-systems. All of the UAV decompositions have a fly UAV function by necessity and for completeness, but the UAV functional decomposition focused on the unique UAV configuration functions needed to support the mission execution. This approach dictates the specifics for the command and control of the UAV concerning flight operations as they were combined into the single function by design. Note each UAV possesses a communications function responsible for receiving and transmitting data to elements external to the UAV. The communications function was also bundled to capture the need for an encrypted data link.

6. Level F-3 IDEF0 Sub-function of Sensor-Enabled Unmanned Aerial Vehicle

The decomposition of the sensor-enabled UAV operation describes the interfaces and functions that enable the mission execution to have radar sensor capability. The sub-functions include producing radar energy, detecting radar energy, identifying incoming threats, and determining target location. These functions describe the sensor-enabled UAV capability to produce refined target measurements as well as threat data that will be used by other UAVs in the swarm. They also identify the radar signals needed to support the sensor-enabled UAV functions within the swarm. See Figure 7 for a depiction of the interactions between sensor-enabled UAV's sub-functions.

1855 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

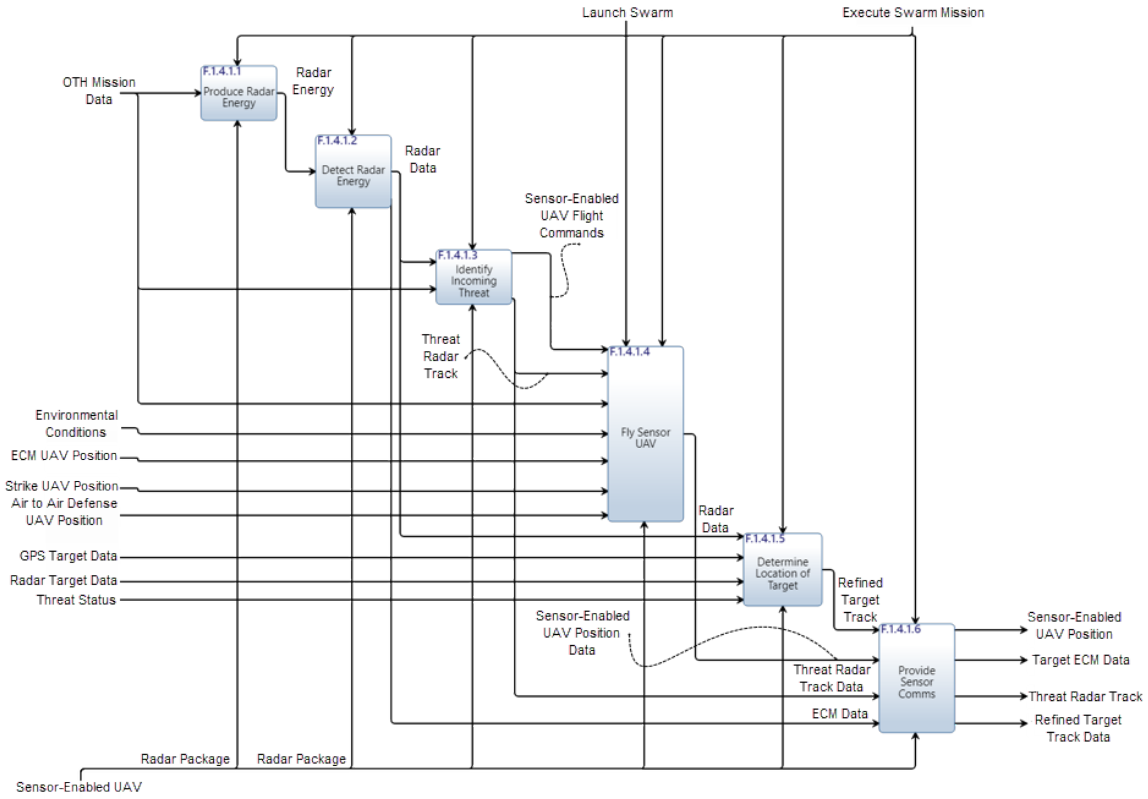

Figure 7. OV-5b for Sensor-Enabled UAV System Sub-functions IDEF0

1856 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

7. Level F-3 IDEF0 Sub-function of Strike UAV

The decomposition of the strike UAV operation describes the interfaces and functions that enable the mission execution to have strike capability. The sub-functions are track target, identify target intercept, launch ordinance, and provide kill assessment. These functions describe the strike UAV capability needed to complete the OTH strike part of the mission. While the swarm is designed to increase the overall mission success, the strike UAV is solely responsible for the delivery of ordinance to the mission target. See Figure 8 for a depiction of the interactions between the strike UAV's sub-functions.

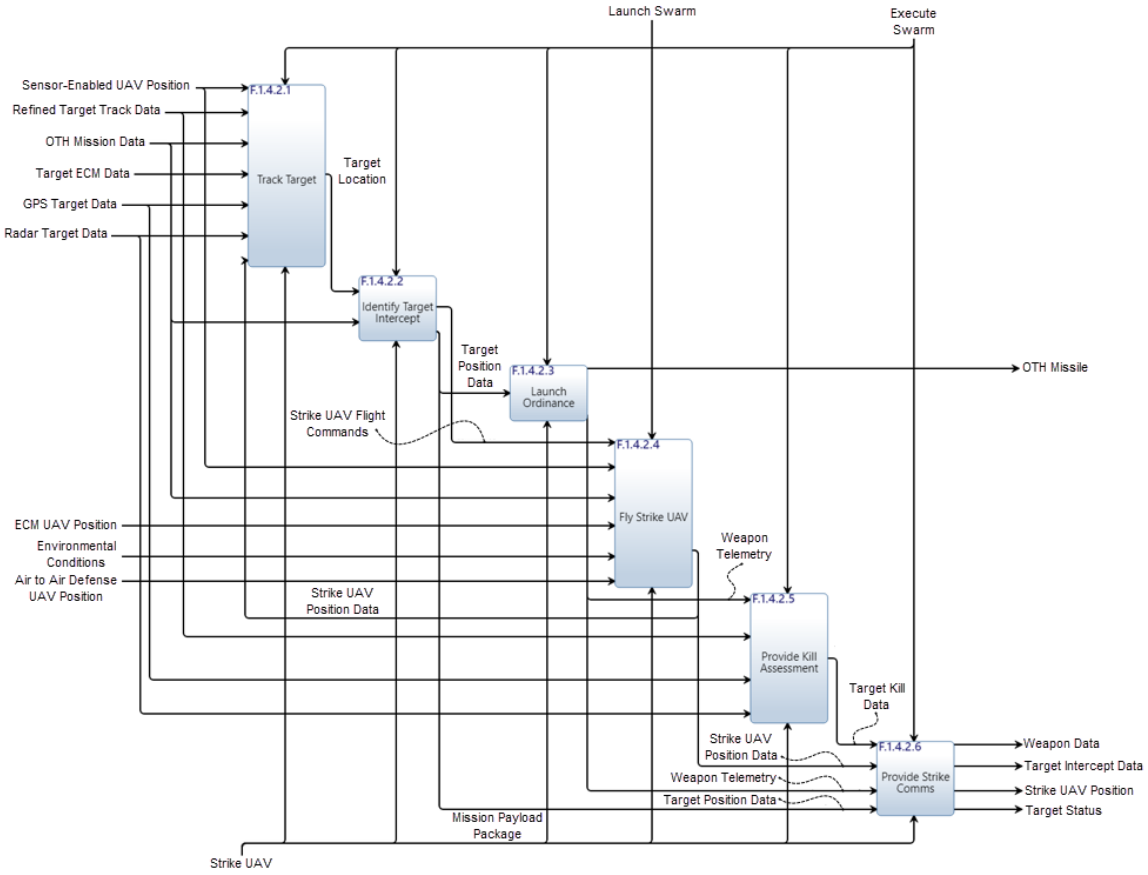

Figure 8. OV-5b for Strike UAV System Sub-functions IDEF0

1857 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

8. Level F-3 IDEF0 Sub-function of Air-to-Air Defense Unmanned Aerial Vehicle

The decomposition of the air-to-air defense UAV operation describes the interfaces and functions that enable the mission execution to have an air-to-air defensive capability. The sub-functions are track inbound threat, identify threat intercept point, launch a missile, and assess threat status. These functions describe the air-to-air defense UAV capability needed to provide the swarm with an air-to-air intercept operation. By eliminating possible threats to the swarm, the overall mission success is improved. See Figure 9 for a depiction of the interactions between the air-to-air defense UAV's sub-functions.

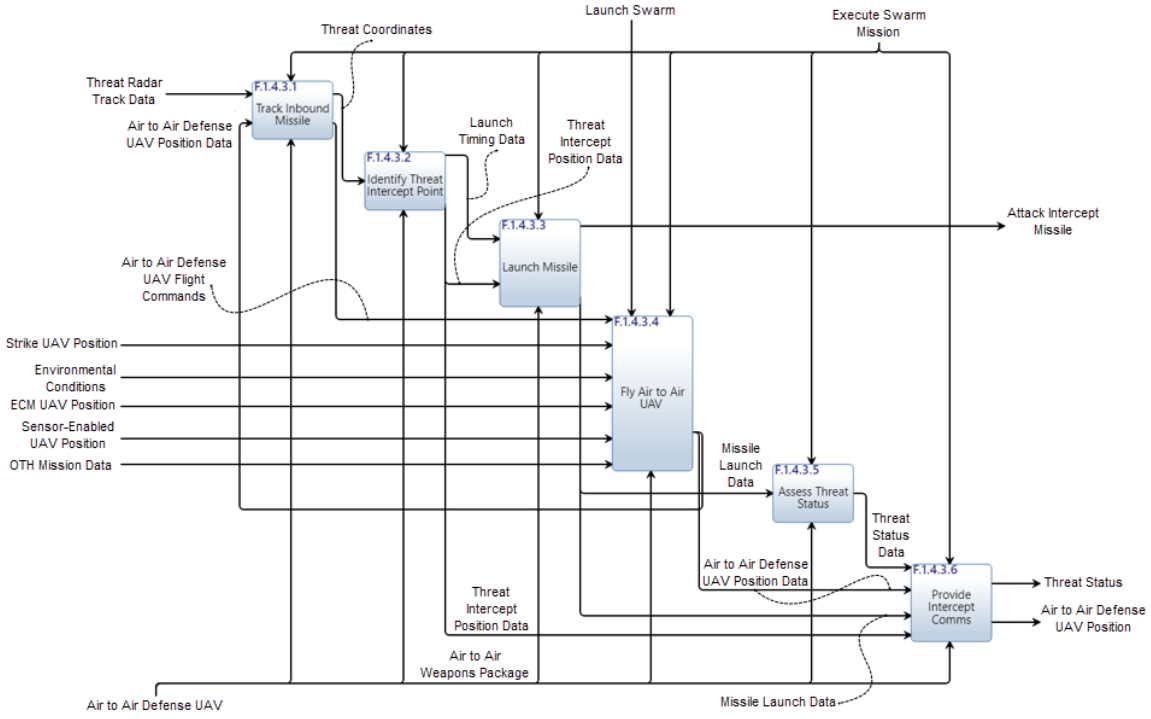

Figure 9. OV-5b for Air-to-Air Defense UAV System Sub-functions IDEF0

1858 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

9. Level F-3 IDEF0 Sub-function of ECM UAV

The decomposition of the electronic countermeasure (ECM) UAV operation describes the interfaces and functions that enable the mission execution to have an ECM defensive capability. The sub-functions include calculating the jamming position and providing the jamming signal. These functions describe the ECM UAV capability needed to provide the swarm with a radar jamming operation. A jamming capability within the swarm can reduce the probability of success for an incoming threat. Decreasing the likelihood of success that a UAV in the swarm is damaged will help improve the probability of success for the overall mission. See Figure 10 for a depiction of the interactions between the ECM UAV's sub-functions.

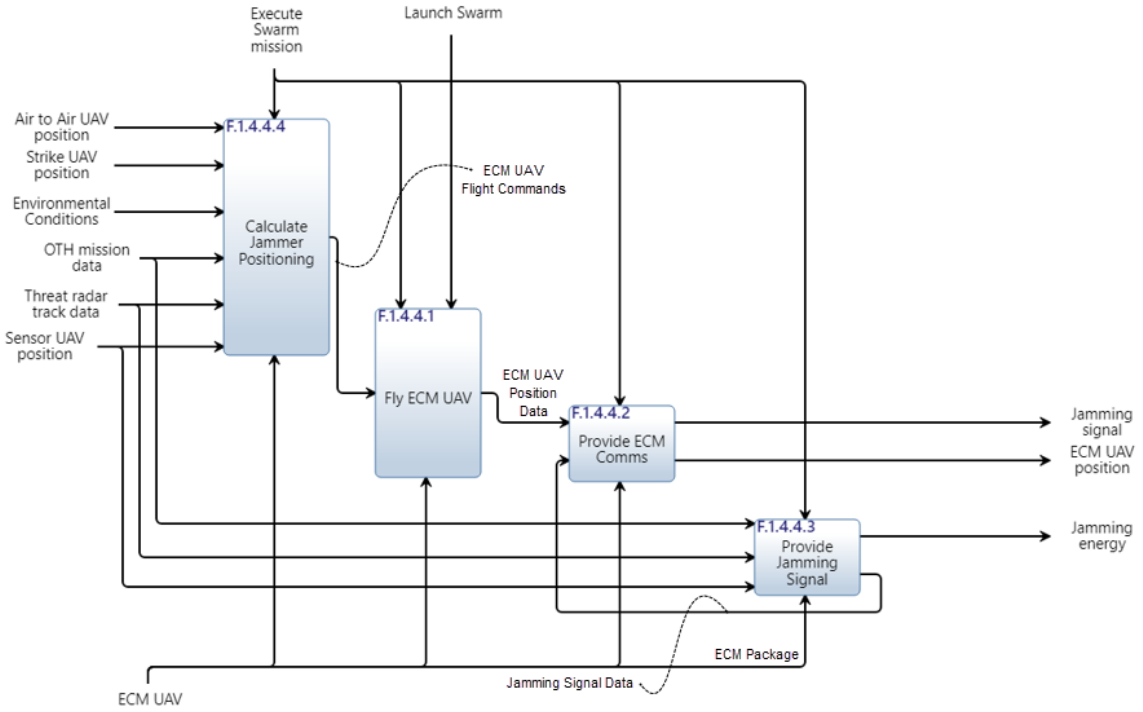

Figure 10. OV-5b for ECM UAV System Sub-functions IDEF0

1859 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The F-3 level of decompositions provides an understanding of the individual UAV capabilities supported through the UAV functional decompositions. This breakdown aided in identifying the sensor, strike, air-to-air, and ECM functions needed to develop the swarm capability. After several iterations of the decomposition, the UAV sub-functions can provide further fidelity in the development of the system architecture. They help define the swarm capabilities as needed to support the mission execution from a unique UAV mission package.

10. OV-6c: Event Trace Description

The OV-6c diagram traces the actions that occur in a given scenario or sequence of events. It provides a time-ordered examination of the resource flow for the swarm scenario as well as the tracing of actions in a critical sequence of events. The mission execution capability is modeled by the set of activities and their attributes. The event trace description captured focuses on the sequence of events completed by the swarm during the execution of the OTH strike mission. It establishes the inter-swarm events by describing the UAV to UAV interactions needed for the execution of the OTH mission. This event trace will be leveraged for the development of the modeling and simulation part of the project. The event trace diagram is shown in Figure 11.

1860 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

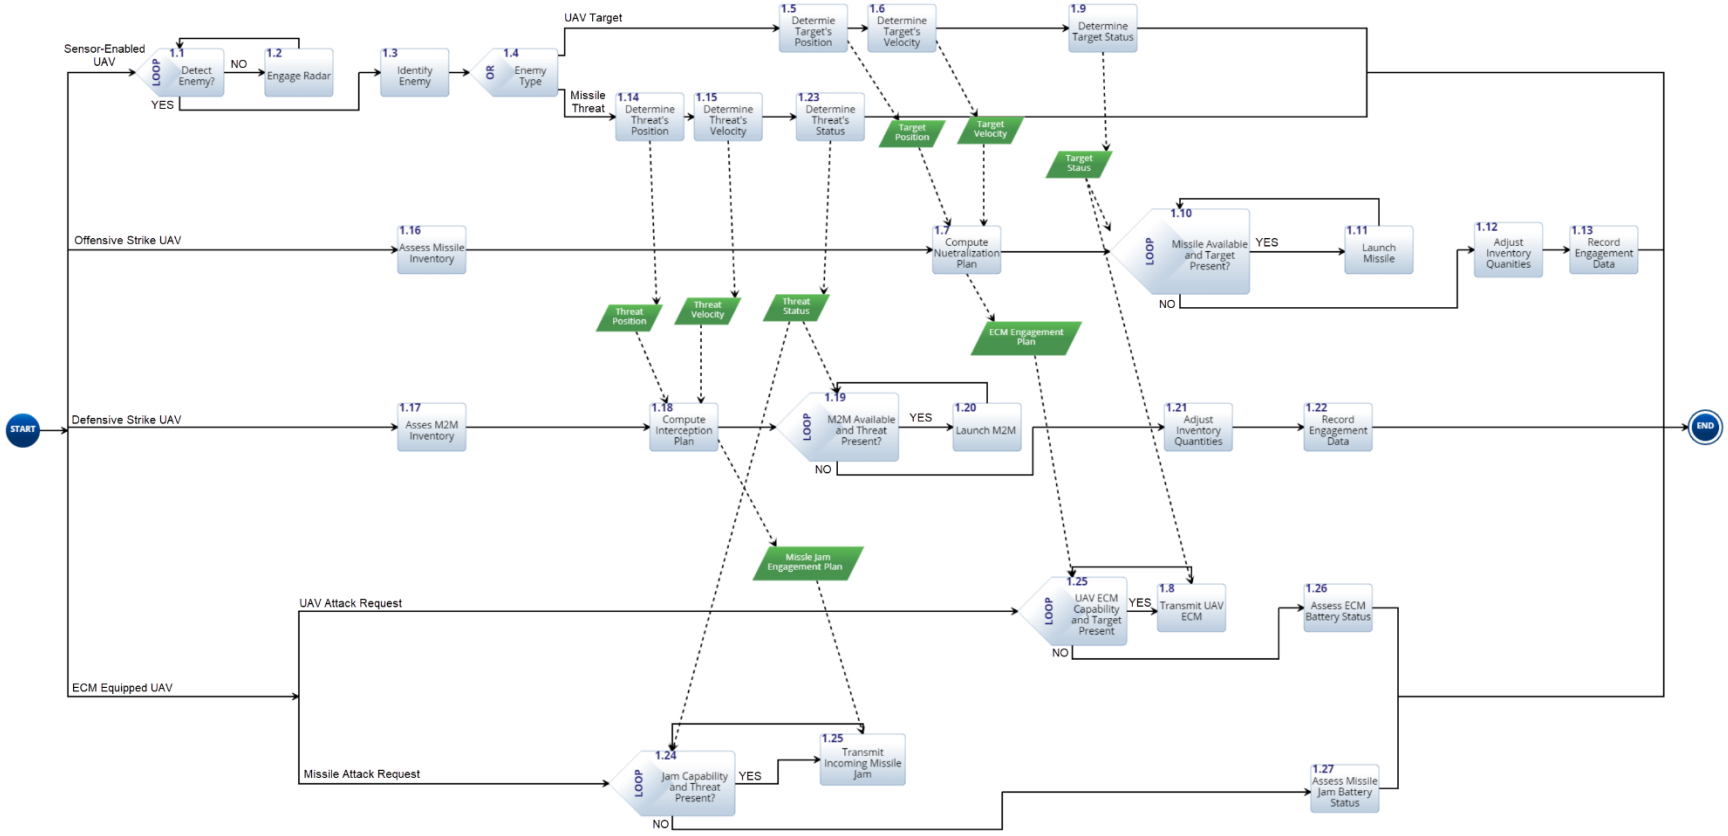

Figure 11. OV-6c Event Trace Description

1861 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

C. SYSTEM ARCHITECTURE

Systems architecture view (SV) describes the system of concern and the connections among the system and subsystems in context with the operational view. The SV allows for evaluation of system operational requirements, evaluation of interoperability issues, and system baselining. As a group, we decided to showcase our system through the use of an SV-1, SV-2, and SV-4 diagram.

1. SV-1: Systems Interface Description

The SV-1 in Figure 12 visualizes the interconnections between the system and its subsystems. The SV-1 depicts the sharing of information between the battlegroup assets. Note the surface ship is acting as a vital node in the relay of this information. The surface ship collects data from GPS satellites, airborne radars, and the UAV swarm. In return, the surface ship relays collected information to each asset as needed. Together, each asset, including the surface ship, is more aware of potential threats in the battlespace than any one asset would be otherwise.

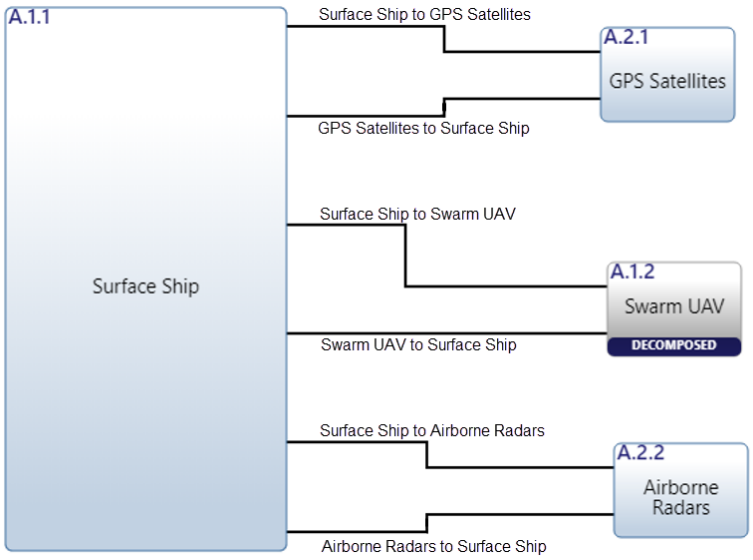

Figure 12. SV-1: Systems Interface Description

1862 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

2. SV-2: Communications Network Diagram

The SV-2 depicted in Figure 13 details the lines of communication between the swarm assets. Note each UAV is connected to the other three UAVs through a secure data link, which allows information sharing to prevent UAV isolation should any UAV be lost to an incoming threat. The network design also allows information to be relayed between UAVs to maintain situational awareness even when assets are spread across the battlespace.

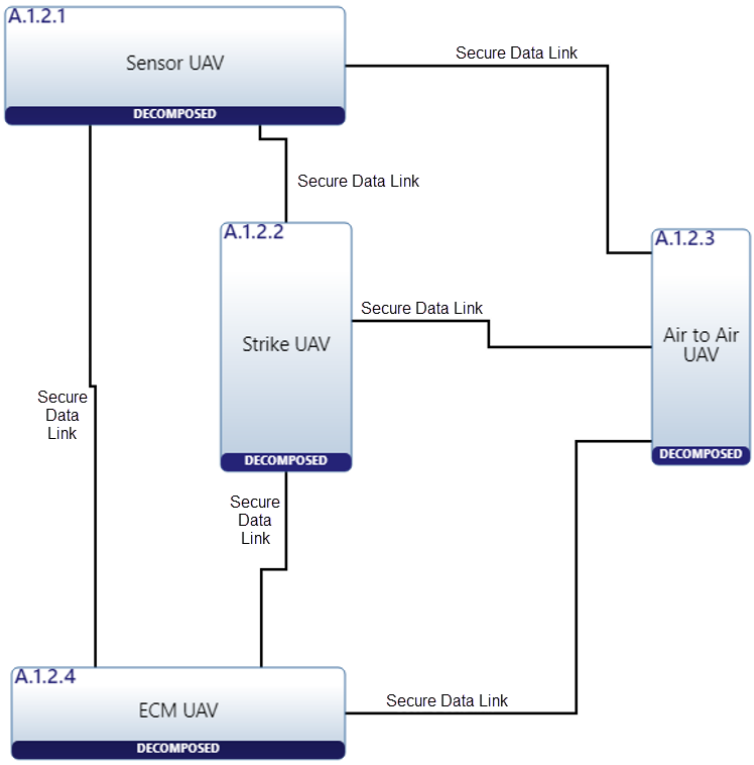

Figure 13. SV-2: Communications Network Diagram

1863 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

3. SV-4: Functional Hierarchy

The SV-4a depicted in Figure 14 details the functional relationships required to support the over-the-horizon mission. Execution of the over-the-horizon mission is supported by the principle functions of the UAVs, which include providing sensor data, strike capability, air-to-air payload, and electronic countermeasures. Each principle function is decomposed to identify the required subfunctions.

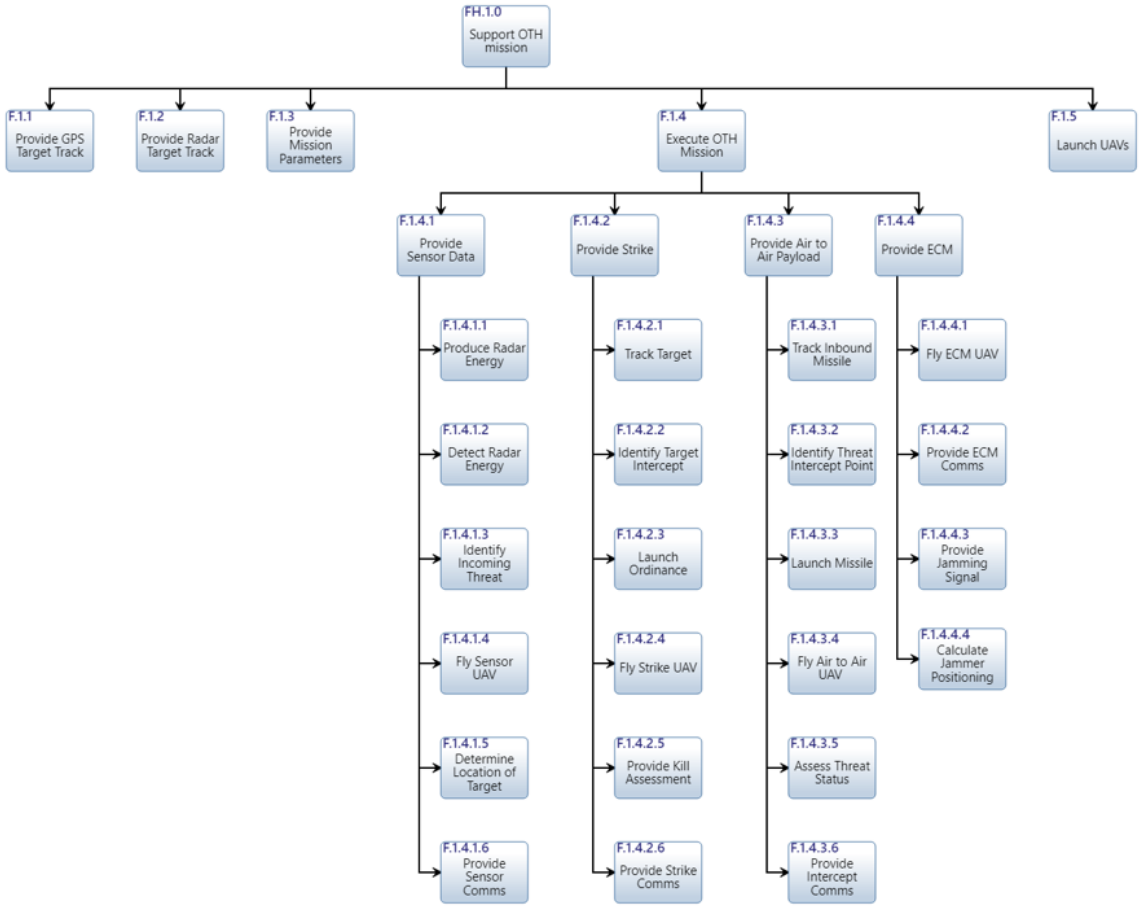

Figure 14. SV-4a: Functional Hierarchy

Reflecting on Chapter III, the operational and system architecture defined to illustrate the relationships required between the swarm assets for mission execution. Chapter IV will culminate the buildup of previous chapters with the modeling and simulation of the OTH mission execution by the UAV swarm.

1865 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

IV. MODELING, SIMULATION, AND, OTH MISSION ANALYSIS

This chapter describes the modeling and simulation (M&S) analysis of the system of UAV systems (referred to as the "swarm") for the OTH mission. It includes a look at cost factors for the utilization of UAVs in the execution of the OTH mission. The chapter contains an overview of the M&S effort and a description of the OTH mission analysis methods employed. The purpose of the model, as well as the model's limitations, will be discussed and followed by a review of the data derived from the model; a similar discourse will follow for simulation development. The execution of the OTH mission using UAVs will then be assessed from a cost-effectiveness standpoint with manned platforms.

A. PURPOSE OF THE MODELING, SIMULATION AND MISSION ANALYSIS

The goal of the M&S and mission analysis was to study the operational benefits of adding UAVs to the OTH mission. The M&S analysis assessed the individual UAV performance factors that are drivers for the OTH mission success. A blue force versus red force OTH mission scenario was modeled. The blue force was equipped with four different types of UAVs: sensor-enabled, air-to-air (A/A), electronic countermeasure (ECM), and strike. The red force consisted of a ship that could return fire with its own set of OTH weapons. The red force ship was the OTH target of the blue force. Mission success consisted of eliminating the red force ship. The performance values of the blue force's individual UAV types were varied, and different combinations and configurations of UAVs were modeled. The cost of the UAV mission implementation was assessed as well.

1. Modeling and Simulation Approach

The approach for the M&S effort is shown in Figure 15. A single scenario for the OTH target mission execution was captured. Then a probabilistic model called the swarm Strike Model (SSM) and the Swarm Strike Simulation (SSS) was developed to represent an instance of the scenario. The results from the SSM and the SSS were compared to establish confidence in the M&S effort. The performance data was then used to analyze the

1866 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

execution of the OTH scenario. This analysis was used to provide evidence for making recommendations about the use of UAV for OTH mission execution.

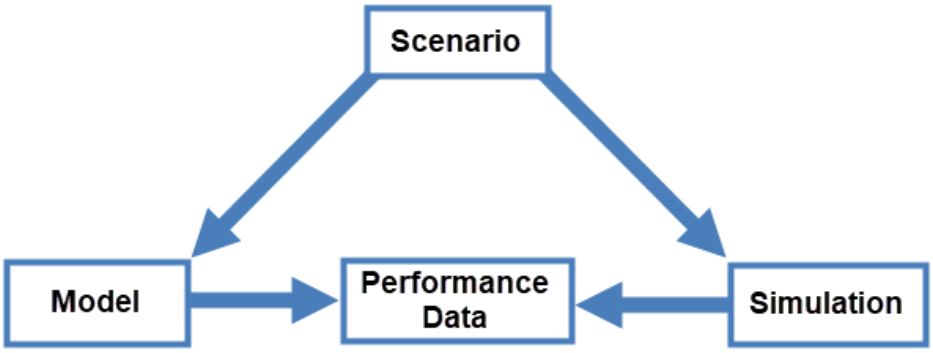

Figure 15. Modeling and Simulation Scenario

2. Modeling and Simulation Scenario

A mission scenario was chosen that represented a blue force OTH strike using a variety of UAV assets onto a red force ship, referred to as the "OTH target." The red force was equipped with its own OTH weapons to fire at the blue force UAVs. Figure 16 is an illustration of the scenario.

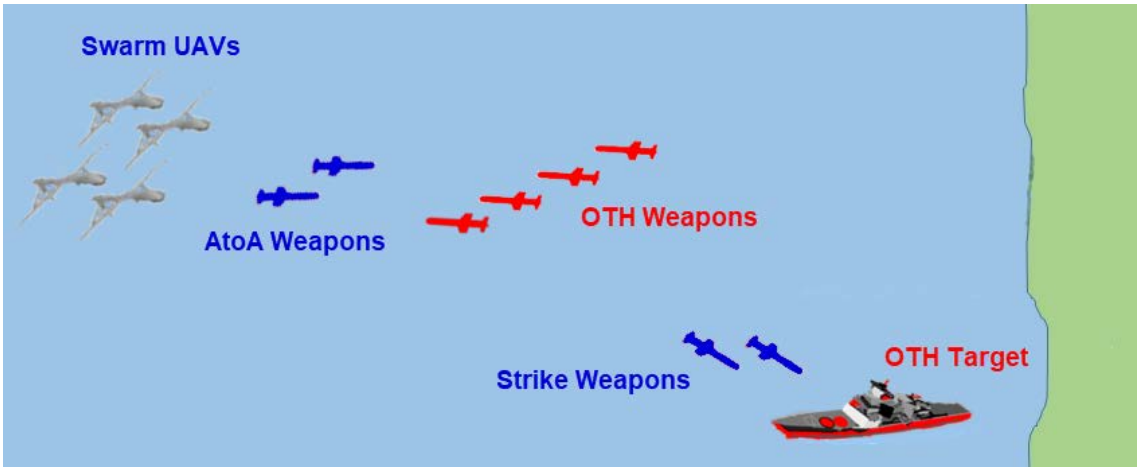

Figure 16. UAV Swarm Engagement Scenario

1867 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The M&S efforts leveraged the UAV types described in the CONOPs and the UAV functional descriptions in the DoDAF architectures. In the mission scenario, the red force "OTH target" can fire on the swarm UAVs during the execution of the OTH-S mission. The scenario outcomes capture the OTH target kill as well as the number of swarm UAVs lost to hostile fire. Successful swarm engagement is defined by the elimination of the OTH target while minimizing swarm UAVs lost to hostile fire. Two critical probabilities were leveraged to evaluate the OTH-S mission success: the probability of striking the OTH target and the probability of a swarm UAV being hit. These two probabilities were central to the series of experiments executed to determine the impact of swarm configurations and UAV performance parameters on engagement success.

The scenario shown in Figure 16 was used to develop the M&S capability. The scenario captures the engagement of the swarm by hostile OTH weapons, as shown in the middle of Figure 16. The inbound threats may be intercepted by the A/A UAV's weapon loadout. The remaining OTH weapons, if any, may be defeated by the jamming energy of the ECM UAV when the ECM UAV is included in the swarm configuration. Any OTH weapons that survive intercept and jamming attempts will have the opportunity to kill a swarm UAV. If the Strike UAV survives the OTH weapons engagement, the UAV will release the strike weapons on the OTH target, as shown in the lower right of Figure 16. The strike weapons will be aided by the sensor-enabled UAV when present in the swarm. Elimination of the OTH target is considered a mission success. Note the scenario detailed above assumes the OTH target environment does not include any factors inhibiting swarm performance.

3. Modeling, Simulation, and Data Analysis Tools

The SSM used for assessing the OTH mission was developed in Excel. This model uses several of the built-in Excel functions including the random number generator and the Binomial Inverse Function, which returns the inverse of the Cumulative Binomial Distribution for a given number of independent trials. These functions allow for probabilistic evaluation of the OTH engagements. The SSM also used the Visual Basic (VB) software in Excel to automate the generation and collection of the swarm

1868 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

configuration data. The SSM's VB script runs every allowable swarm configuration and captures the probabilities affecting mission success for each run.

Confidence in the SSM was increased upon comparing the results from the SSM to those obtained from the SSS. The SSS created for this purpose, which was developed in ExtendSim, captures a time-based execution of the OTH mission scenario. The ExtendSim functions for normal distribution time delays, random number generation, and probabilistic branch selection were used to produce the metrics required for comparable assessment of the OTH scenario.

The M&S effort used both the Excel and Minitab statistical analysis tools to assess data generated. Excel was used to calculate the variance and confidence intervals for the data produced by the SSM. The statistical tools in Minitab were used to generate the design of experiments for the UAV performance parameter analyses. Minitab was also used to generate the main effects analysis using the data from the design of experiments (DOE) executions. The role of each tool in the M&S effort is summarized by the flowchart shown in Figure 17.

1869 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

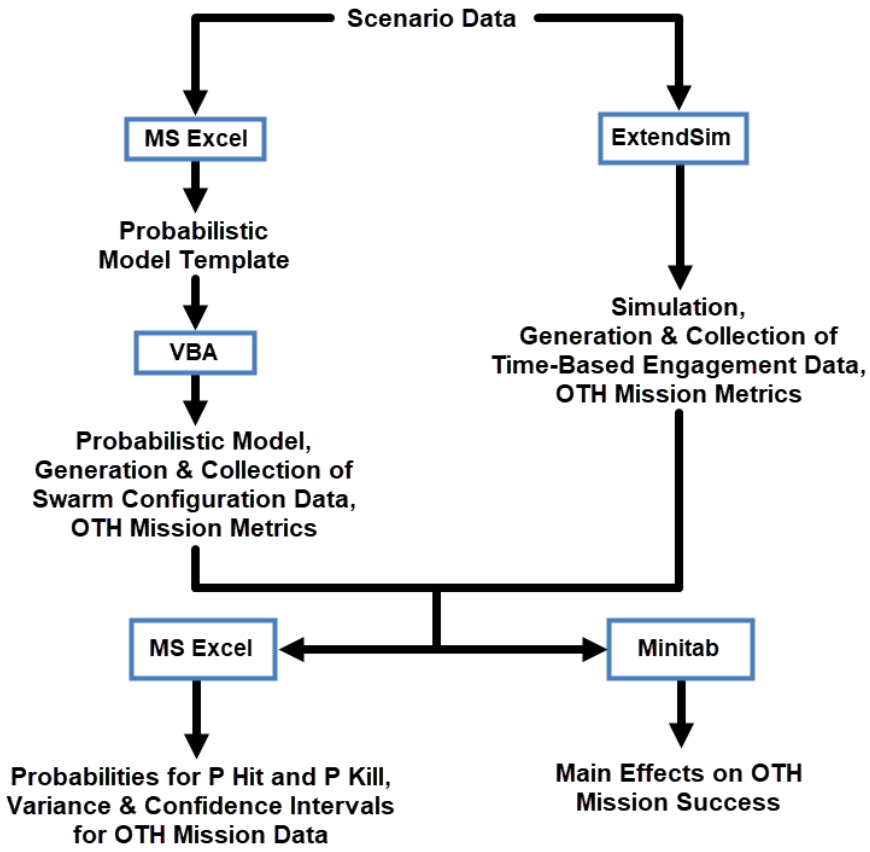

Figure 17. Modeling and Simulation Flowchart

4. Assumptions and Constraints

Several assumptions were made at the onset of the project. For instance, the scenario assumes a single hit to a swarm UAV, the OTH target, or OTH weapon will result in a kill of the targeted asset. In addition, the OTH target position is assumed known prior to swarm launch and will not loiter outside the effective range of the swarm. Note the current SSM and SSS builds neglect adverse effects in the OTH target environment, such as severe weather and geographical influences. Swarm UAV reliability is also neglected.

Both SSM and SSS are constrained to a single OTH target engagement per scenario execution. The OTH weapon performance, percent of kills per engagement, is defined in terms of threat probability of kill (threat P_k) in both the SSM and SSS. Threat P_k in the M&S was held constant at 70 percent throughout scenario execution. The SSM was constrained to having a maximum of five of each UAV type in the mission. This was done

1870 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

to manage the complexity of the SSM in relation to its capability for assessing swarm sizes. One functional constraint is that the SSM does nothing to prevent the OTH weapons from targeting the same UAV multiple times. The SSS was developed to have a single configuration of each UAV in the swarm during the scenario execution. This was done to manage the complexity of the SSS and focus on the assessment of the UAV specific performance factors.

5. Modeling and Simulation Capabilities

The M&S effort developed both the SSM and the SSS as a means to provide more fidelity in the OTH mission analysis. A full comparison of the SSM versus the SSS capabilities is shown in Table 3.

Table 3. M&S Capability Comparison

Capability	Modeling	Simulation
UAV performance factors	Included	Included
Swarm UAV configurations	Variable	1 each
OTH target	Single	Single
OTH target weapons loadout	Variable	Set to 4
OTH weapons targeting order	Based on RCS	Based on RCS
OTH weapons targeting fidelity	Low	Medium
OTH weapon performance	Set to 70%	Set to 70%

The low assessment for the SSM targeting fidelity reflects a limitation inherent to the model that allows the continued targeting of a downed UAV. The model's targeting fidelity is further reduced by the instantaneous assessment of all engagements, which negates the effects of volley timing and follow-on target selection. The SSS targeting fidelity was assessed as medium due to the inclusion of a timing component. The timing component allowed for the downing of the A/A or ECM UAV at mission onset. The loss of these UAVs decreased the swarm's defensive capabilities and the OTH weapons were able to target another UAV with a greater kill probability. The SSS targeting fidelity was not assessed as high due to the complexity preventing multiple swarm configurations to be

1871 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

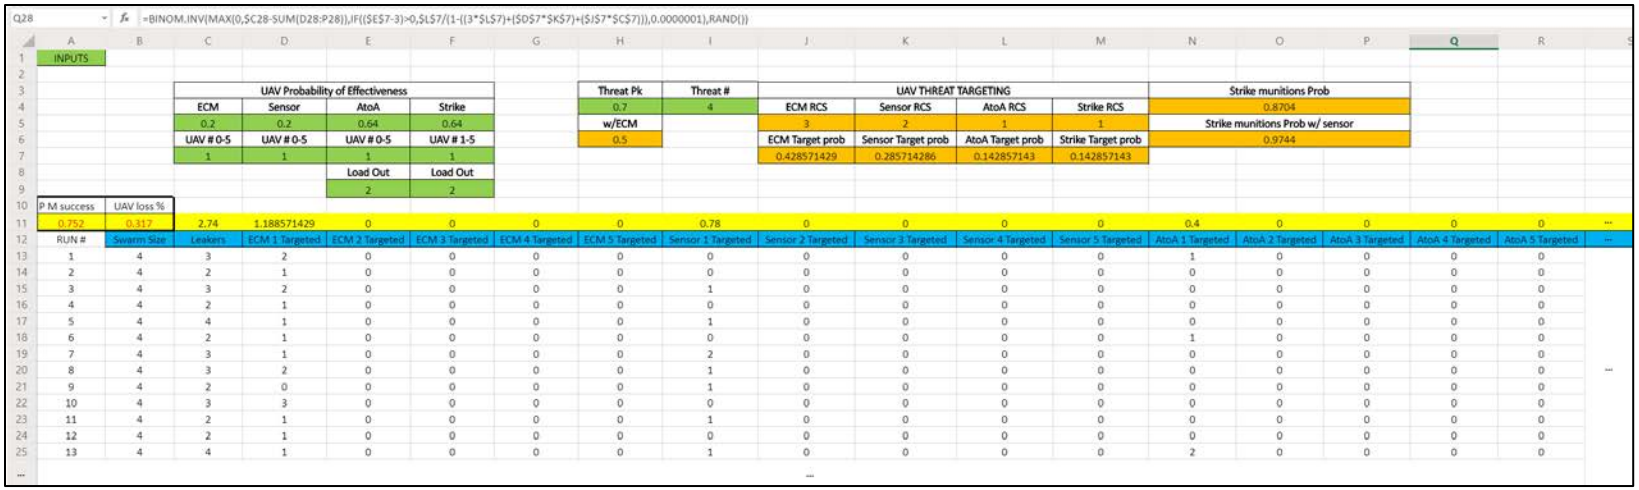
readily assessed. As such, only one UAV of each type was represented in the swarm configuration for the simulation effort.

B. DESCRIPTION OF THE MODEL

1. Model Parameters

Weapon performance values are integral to the UAV performance analysis and drive the target kill assessment. The success of a weapon's engagement is quantified by the probability of target intercept, the probability of target elimination upon intercept, and the overall weapon reliability. Factors affecting the performance of assets assigned to the Strike and A/A UAVs are accounted for in their respective success probabilities. Factors affecting the probability of effectiveness for the sensor-enabled and ECM UAVs are accounted for in each UAV's net contribution to the swarm. The sensor-enabled UAV's probability of effectiveness reflects the UAV's ability to enhance the intercept of A/A UAV's intercept of OTH weapons as well as the Strike UAV's probability of OTH target hit. Likewise, the EMC UAV's probability of effectiveness reflects the UAV's ability to degrade the performance of inbound OTH weapons. The M&S efforts did not account for factors affecting UAV reliability, thereby allowing for an engagement success value of 1. Known reliability events could be integrated by multiplying the engagement probabilities by the reliability value of the swarm UAV.

Using the CONOPs and system architecture developed for the OTH mission as a foundation, the team developed the SSM for the swarm OTH engagement scenario. The SSM allows for the assessment of swarm size and selection of UAV assets as well as analysis of individual UAV performance. These metrics are captured in the SSM and expressed in terms of probability of relative success.



There are several probability factors included in the SSM, such as the probabilities for targeting order for OTH weapons. The UAV targeting probabilities are based on assumptions developed from a radar cross-section (RCS) analysis of the UAVs. An inbound OTH weapon is expected to target the ECM UAV with the sensor-enabled UAV being the next likely target. The remaining OTH weapons would give the A/A and strike

1872 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

UAVs equal priority. The ECM UAV is thought to be the priority target for the OTH weapons as the UAV's escort jamming capability is most effective with the UAV in front of the swarm. The ECM UAV is likely the first UAV targeted by the OTH weapons due to its jamming signal transmission and lead formation position. The sensor-enabled UAV's employment of radar to enhance the OTH firing solution also generates considerable radar signature thereby placing the UAV next OTH weapon's targeting order. The A/A and strike UAVs have a similar configuration and asset loadout, which allows the UAVs to share the lowest position in the targeting order.

The probability that a hostile force would target and eliminate a swarm UAV is dependent on the engagement values and performance of the OTH weapons. Successful engagement of the A/A weapons reduces the number of inbound threats. Likewise, the employment of the ECM UAV function minimizes the probability that a hostile threat will be successful in killing a swarm UAV. Once the probability of a successful OTH weapon engagement has been evaluated, and the fallout of the intercept attempt realized, the number of UAV casualties per scenario execution is used to determine the probability of the UAV hit (P_{Hit}) metric. Next, the SSM predicts the success of the OTH target kill using the remaining strike UAVs weapons available. The OTH target kill success is used in the calculation of the probability of success ($P_{Success}$) metric. An excerpt from the SSM is shown in Figure 18.

Figure 18. Swarm Strike Model Excerpt

1874 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The orange boxes shown in Figure 18 highlight the calculated values used in the execution of the scenario. These values are not altered by direct input; however, several values are linked to input values and may vary as a result. The targeting probability values, shown below the probability cells, are mathematically defined by RCS in the targeting process.

The UAV performance inputs and OTH weapons performance parameters are shown in Table 4. These values are also shown in the light green boxes of Figure 18. In addition to these values, the table captures the allowable range for the SSM inputs.

Table 4. Swarm Strike Model Input Parameters

UAV Probability of Effectiveness				
	ECM	Sensor	A/A	Strike
Range	0.01-0.99	0.01-0.99	0.01-0.99	0.01-0.99
	Swarm Configuration			
	ECM	Sensor	A/A	Strike
Range	0-5	0-5	0-5	1-5
	UAV Weapons		OTH Weapons	
	Strike Loadout	A/A Loadout	Threat Pk	Threat Load-out
Range	0-4	0-4	0.7	0-4

The range values shown in Table 4 were used to calculate asset-specific probabilities. While the full range shown in Table 4 is allowed in the SSM execution, the probability of effectiveness for a given platform is bounded by operational effectiveness parameters as well as reliability factors. These bounds were defined by the performance assessments conducted on each UAV platform. The number of weapons a UAV may carry is not mathematically restrained in the SSM; the values shown reflect the range considered for the scenario assessment. Once the SSM functionality was confirmed, a study of the output variance was conducted to assess the consistency of the results.

The data in Table 5 shows the variance in the SSM outputs for $P_{Success}$ and P_{Hit}.

The number of model trials was gradually increased from 100 to 500 runs per engagement. All inputs for the SSM were held constant during the increase of trial runs. A selection of 20 samples was collected at the higher trial count for statistical analysis. As shown in Table 5, the observed variance decreases as the number of trial runs increases per

1876 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

engagement. The variances were then used to calculate the 95 and 99 percent confidence intervals. The benefit of adding additional trial runs on $P_{Success}$ output decreases significantly from 350 to 500 runs. Based on the minimal difference in obtained data and the increased time required to run the SSM, a run size of 350 was selected for the remaining analyses.

2. Model Runs for UAV Performance Factors

The SSM established six UAV performance factors. The ECM and sensor performance, as well as loadout, A/A, and strike weapon performance, were assigned values of estimated effectiveness on a scale from zero to one; a value of zero represents no effect and a value of one would be completely effective. For instance, an effective range of 0.20 to 0.50 was estimated for the ECM UAV while the sensor UAV was assigned an effective range of 0.20 to 0.50. Using the six UAV performance factor inputs to the SSM, a 2-level factorial design of experiments (DOE), with a 1/8 fraction and a single center point per cube, was developed. The performance modeling inputs and outputs for the DOE are captured in Table 6.

Table 6. UAV Performance Modeling DOE

P_{ECM}	P_{Sensor}	$P_{A/A}$	P_{Strike}	Strike Loadout	A/A Loadout	$P_{Success}$	P_{Hit}

1877 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Referring to Table 6, the ECM P-value relates to the degradation in the performance of an inbound OTH weapon as caused by the ECM UAV. On the offensive, the sensor performance (Sensor P) value represents the enhancement of the strike weapon's performance afforded by the sensor-enabled UAV. The A/A and strike performance (Strike P) values represent the probability of hit for each weapon in the A/A and strike UAV loadout. The strike and A/A loadout values capture the total number of weapons in the swarm as equipped by the respective UAV platform.

The swarm configuration was maintained at one UAV of each configuration to ensure that multiple UAVs of the same platform did not weigh the performance parameters. The OTH weapons loadout was set to four to present a stressing engagement for the swarm. The results of the DOE were evaluated in Minitab. The main effects for the probability of OTH hit ($P_{Success}$) and the probability of UAV hit (P_{Hit}) are captured in Figures 19 and 20.

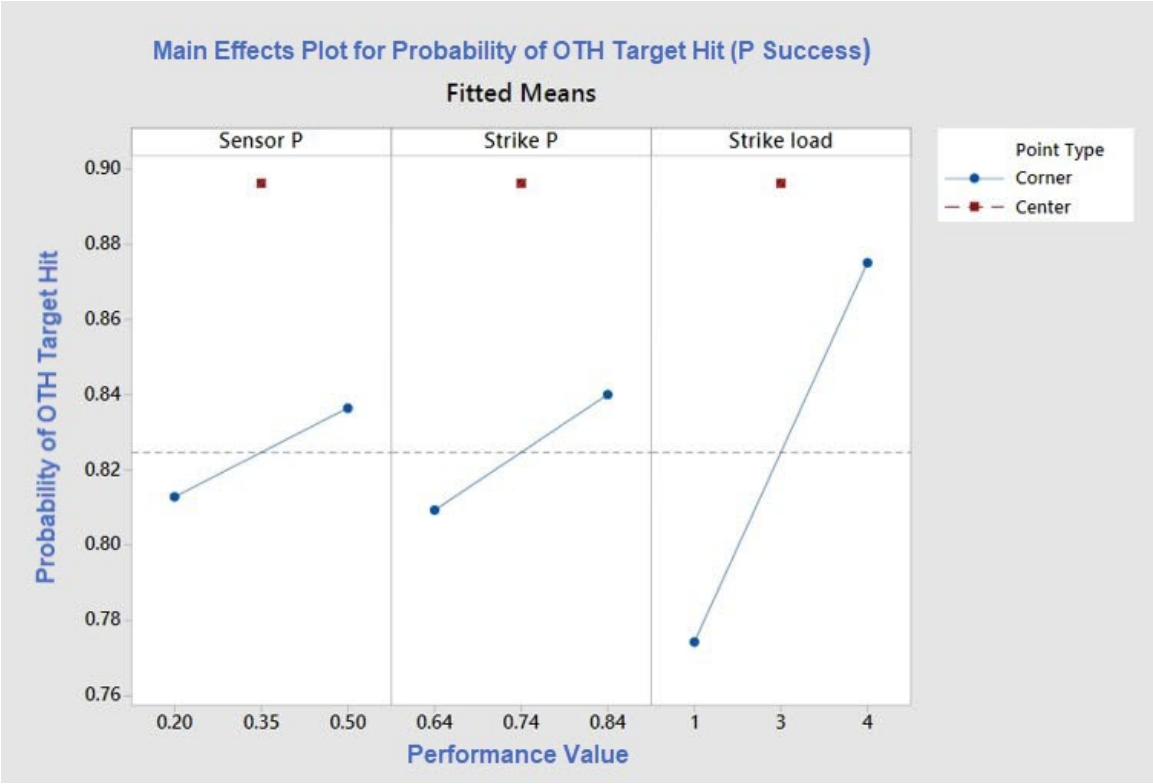

Figure 19. Engagement Probability of Success Main Effects

1878 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

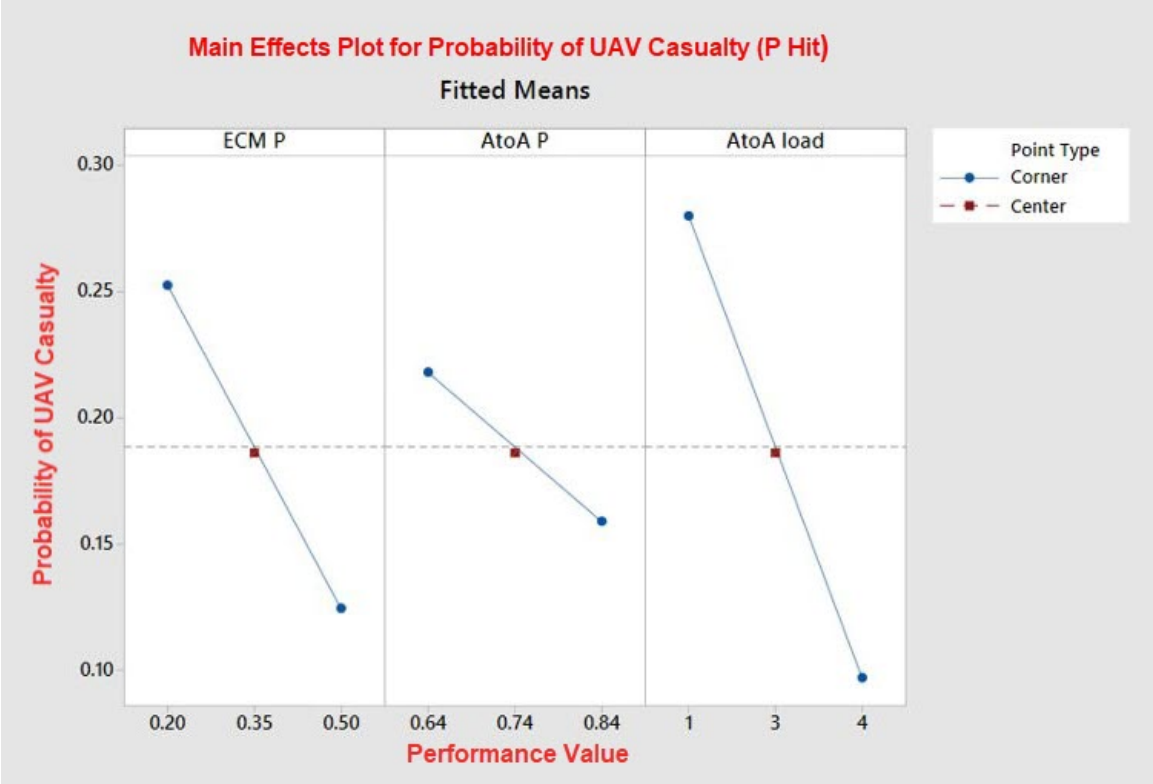

Figure 20. Engagement Probability of Hit Main Effects

The slope of the line in the main effects plots captures the impacts of the UAV performance factors on the engagement criteria. The plots show that increasing the strike loadout has the most significant impact on the probability of OTH hit. While increasing the A/A loadout has the most significant impact on the probability that a UAV is hit. The overall engagement was evaluated, and the SSM is predicting that UAV survivability is driving $P_{Success}$ for the OTH engagement.

3. Model Runs for Swarm Configurations

Utilizing the swarm configuration capability of the SSM, a two-level factorial DOE with a 1/8 fraction and a single center point per cube, for the swarm size was developed in the Minitab software tool. The model inputs and outputs for the swarm size DOE, shown in Table 7, cover the analysis of a mission where the OTH target has a loadout of four weapons.

0	5	5	1	0.963

1880 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The combination of each of the UAV configuration numbers equates to the total swarm size for the engagement. The performance inputs remained constant at 0.2 for the ECM and sensor, while the A/A and strike weapons performance values were set to 0.64. The A/A and strike loadouts were set to two each. The swarm size was evaluated for an OTH weapons loadout of zero, or non-stressing, and loadout of four, a highly stressing engagement. The results of the DOE were evaluated in Minitab. The following three figures capture the main effects for the probability of OTH hit ($P_{Success}$) based on the red force OTH loadouts of zero (shown in Figure 21) and four (shown in Figure 22) as well as the probability of UAV hit (P_{Hit}) for an OTH loadout of four (shown in Figure 23).

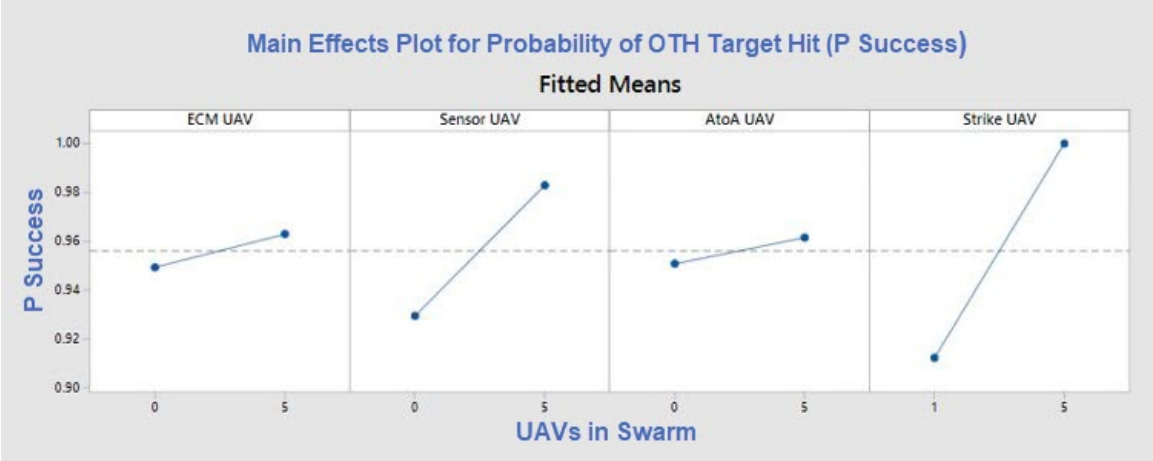

Figure 21. Probability of Success Main Effects for Red Force with No Return Fire Capability

The main effects plots for the modeling parameters show the strike UAV is the performance driver for the scenario in which the red force has no return fire capability. The A/A and ECM UAVs have a negligible impact in this scenario since there are no OTH weapons to act upon.

1881 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The main effects plot in Figure 22 shows all UAV configurations are significant in the scenario where the red force can return fire using four weapons. As seen in Figure 22, increasing the number of strike UAVs has the most significant positive impact on mission success. A swarm consisting of five strike UAVs provide additional opportunities for engagement of the OTH target. However, a UAV swarm consisting solely of strike UAVs is more susceptible to casualties and is not ideal.

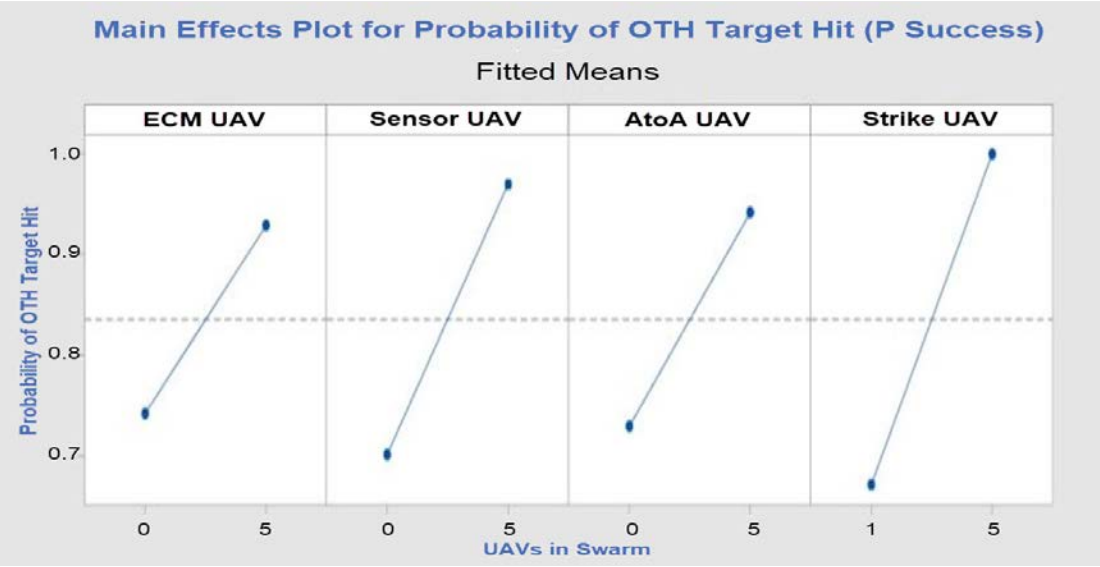

Figure 22. Probability of Success Main Effects for Red Force with Four Return Fire Weapons

The main effects plots in Figure 23 show that the UAV hit (P_{Hit}) performance driver for the four fire OTH engagement is the A/A UAV. The sensor and strike UAVs have an equivalent impact on P_{Hit} due to the constant OTH weapons having an increasing number of targets. However, increasing the number of A/A UAVs has the most significant positive impact on the P_{Hit} criteria for mission execution.

1882 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

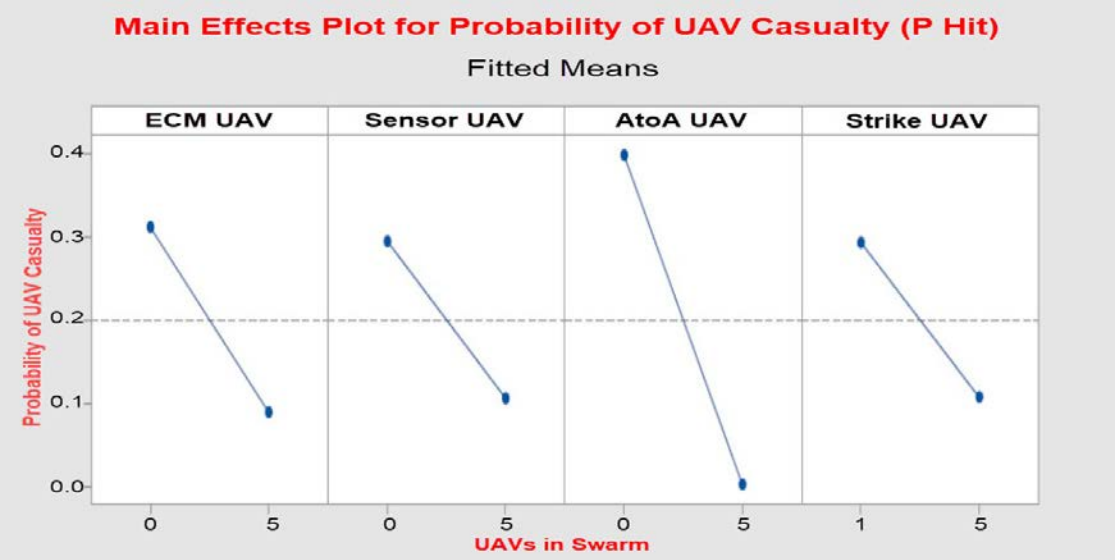

Figure 23. Probability of Hit Main Effects against Red Force with a Return Fire Capability of Four Weapons

4. Lookup Table Model of Swarm Configurations

The SSM was also used to produce a table of swarm configurations as a lookup table for the execution of a set of OTH engagements, as shown in Table 9. This table was developed by evaluating the OTH return fire capability shown in the threat column. The swarm configurations were chosen by maximizing the probability of OTH hit ($P_{Success}$) while minimizing the values of UAV hit (% UAV loss) and reducing the UAVs committed to each engagement to ensure the highest number of missions could be completed.

Table 9. Swarm Configuration for OTH Engagement

Threat No.	ECM No.	Sensor No.	A/A No.	Strike No.	$P_{Success}$	P_{Hit}	Swarm Size
0	0	1	0	1	0.986	0.000	2
1	1	1	1	1	0.963	0.014	4

4	0	1	2	2	0.969	0.170	5
4	1	1	1	2	0.966	0.260	5

1883 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The data in Table 9 represents the recommended swarm sizes for deployment against OTH targets that have a known return fire capability. For an OTH target without return fire capability, the SSM is predicting that a swarm configuration of one sensor and one strike UAV will have a 98% probability of target kill. The prediction for the stressing scenario includes two swarm configurations with good probabilities for the scenario metrics of $P_{Success}$ and P_{Hit}. The determining factor in using one swarm configuration over another is made when planning the likelihood of follow on missions. Choosing to deploy a swarm consisting of a single A/A UAV allows an additional OTH mission to be accomplished using an A/A UAV in the swarm.

C. SIMULATION ANALYSIS

The SSS executes the single OTH target engagement with the same mission performance parameter outputs as the SSM. The UAV performance simulation the SSS for the OTH engagement was developed to increase the fidelity of the performance data analysis. The OTH engagement in the SSS was developed in two parts. The first part captures the incoming fire of the OTH weapons. The second part evaluated the engagement of the OTH target based on the surviving swarm UAVs. The SSS includes functionality that disables the targeting and capabilities of UAVs that have been hit by the OTH salvo.

The SSS is shown in Figure 24 was used to conduct an additional assessment of the UAV performance factors. This data was used to build confidence in the modeling results as well as provide further evaluation of the scenario success drivers based on UAV performance factors.

1884 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

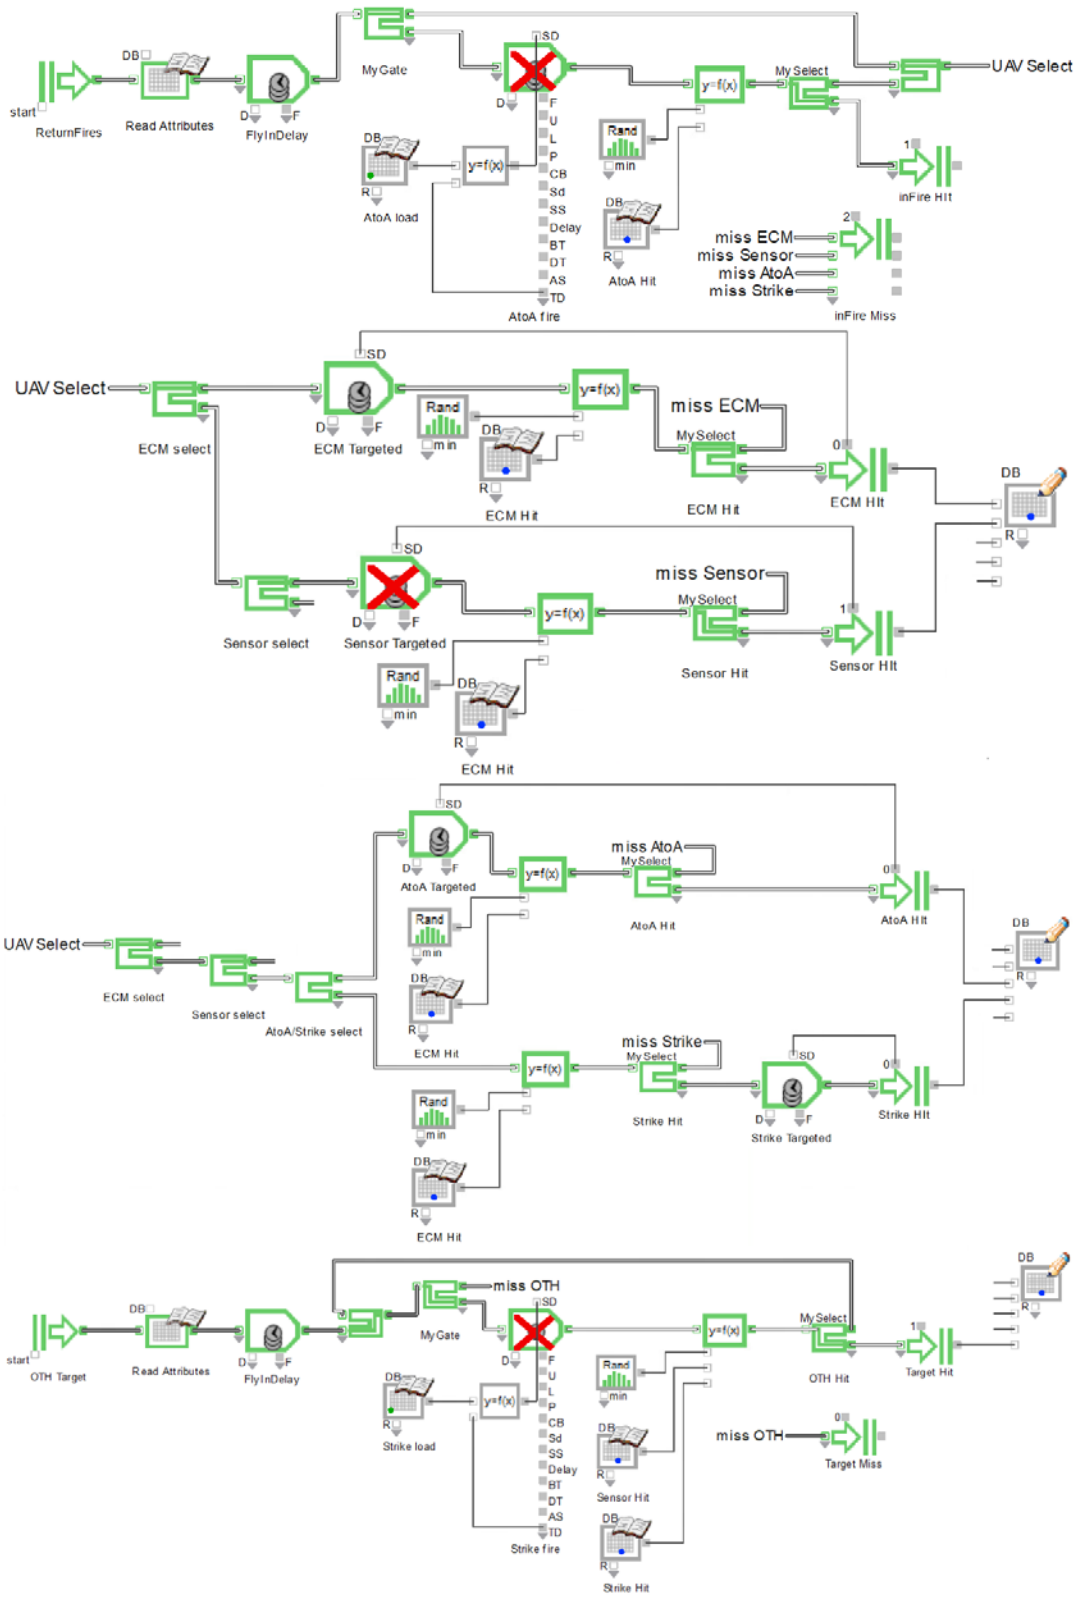

Figure 24. Swarm Strike Simulation

1885 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

When the SSS functionality matured, 20 runs of data were collected using the same performance parameters as the model data from Table 5. This data is shown in Table 10. The variance from the SSS for the $P_{Success}$ is smaller than the SSM which shows that the simulation has a more repeatable assessment of $P_{Success}$. The variance from the SSS for the P_{Hit} is larger than the SSM which shows that the model has a more repeatable assessment of P_{Hit}. The P_{Hit} variation could be due to the higher fidelity implementation of the UAV targeting in the SSS.

1886 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The run data from the variance assessment was used to compare the mission performance outcomes ($P_{Success}$ and P_{Hit}) averages using the Excel t-test function with unequal variances. The t-test data in Table 11 shows that the SSM and SSS are producing different results for the mission outcomes. This was expected, as the refinement provided by the SSS should have a significant impact on the mission outcome.

Now that the SSS fidelity has been assessed, the OTH mission can be analyzed. This was done through the execution of the performance DOE parameters from the modeling assessment shown in Table 6. The DOE parameters were run through the SSS with 350 executions per row. Table 12 shows both the DOE inputs and outputs for the UAV performance in the SSS.

Table 12. Swarm Strike Simulation UAV Performance DOE

P_{ECM}	P_{Sensor}	$P_{A/A}$	P_{Strike}	A/A Loadout	Strike Loadout	$P_{Success}$	P_{Hit}
0.20	0.50	0.64	0.64	1	4	0.651	0.414
0.20	0.50	0.64	0.84	4	1	0.800	0.193
0.20	0.20	0.84	0.64	4	4	0.951	0.089
0.20	0.20	0.84	0.84	1	1	0.606	0.419
0.50	0.20	0.64	0.64	4	1	0.774	0.087
0.50	0.20	0.64	0.84	1	4	0.837	0.192
0.35	0.35	0.74	0.74	3	3	0.897	0.156
0.50	0.50	0.84	0.64	1	1	0.797	0.181
0.50	0.50	0.84	0.84	4	4	0.980	0.036

The performance results from the SSS reinforce the performance analysis from the SSM. This increases the confidence that the analysis and findings from the modeling effort are useful. The DOE analysis from Minitab produced the same main effects results that were observed in the modeling analysis. These effects are shown in Figures 25 and 26.

1888 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

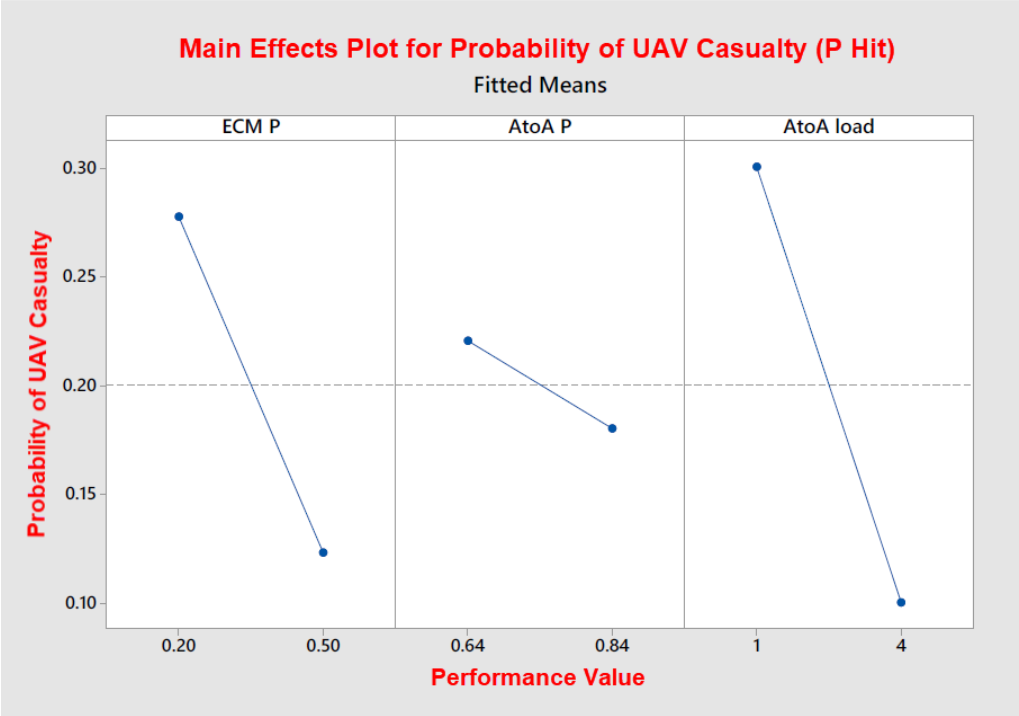

Figure 25. Swarm Strike Simulation Probability of Hit Main Effects Plot

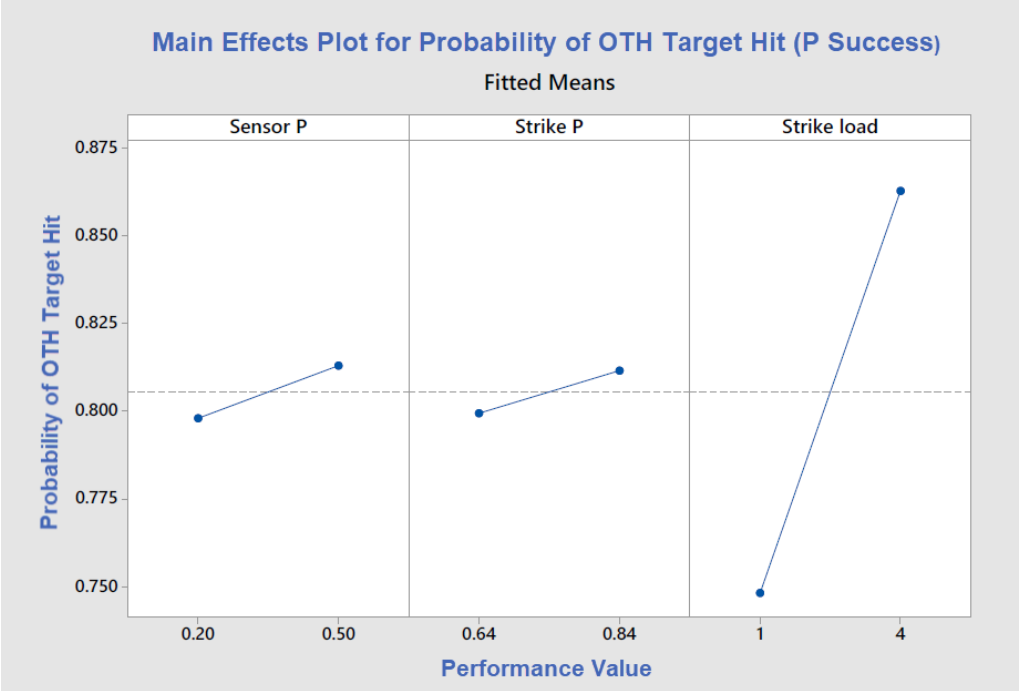

Figure 26. Swarm Strike Simulation Probability of Success Main Effects Plot

1889 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

This simulation could be utilized to further explore the UAV performance through the addition of an extended time delay for the engagements, which was not captured in this data. If the time between the release of the OTH weapons was lengthened to the point where an A/A UAV was hit, the swarm capability to intercept the next weapon would be reduced. This could result in changes to the performance driver analysis.

The M&S effort produced data that was well-matched and provided confidence that the scenario is producing believable results. It also provided the performance assessments for this project. Based on the development and assessment of the M&S tool, a usable table of swarm configurations was developed. The UAV performance factors that were identified as scenario success drivers helped identify critical UAV capabilities within the swarm. The data and analyses developed can be used to help inform the development of a BREM swarm capability.

D. COST ANALYSIS

With the move towards the usage of UAVs for combat, it is important to look at the cost implications. In a 2012 study, the average unit cost for a Lockheed Martin F-22 Raptor was approximately $186M (Boyle 2012). In addition, the average yearly cost for operations and support for each aircraft was approximately $11.5M with each flight hour costing the military $11.5K (Boyle 2012). Likewise, the Lockheed Martin F-35 Lighting II has an estimated unit cost of $91M with an average yearly operations and support cost of $5M per aircraft (Boyle 2012); current estimates expect the Lighting II's cost per flight hour to be reduced to $25K (McCarthy 2018). The premier electronic attack platform, the Boeing EA-18G Growler, costs an estimated $70M per unit (Defense Acquisition Management Information Retrieval 2017) with an average yearly operations and support cost per aircraft of approximately $6M; the cost to operate the Growler per flight hour is $25K (Defense Acquisition Management Information Retrieval 2017). With the high unit and operational and support costs, it is worth considering the cost-benefit of tasking UAV platforms to fulfill these critical roles.

From the same 2012 study, the unit cost for a General Atomics MQ-1C Gray Eagle was cited at $26.5M with an average yearly operations and support cost of $8M per unit,

1890 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

per year (Boyle 2012). Similarly, the General Atomics MQ-9 Reaper was reported to have a per-unit cost of $6.5M per unit with operations and support cost of $3M per unit, per year; the per flight hour cost for the Reaper is estimated at $3.25K (Boyle,2012). Likewise, the Northrop Grumman RQ-4 Global Hawk's has an average unit cost was $103M with an operations and support cost of $15.6M per unit, per year; the per flight hour cost for the Global Hawk is estimated at $31K (Boyle 2012). Table 13 summarizes unit and flight-hour costs.

Table 13. Cost Comparison of Manned and Unmanned Platforms

Mission Role	Strike/A/A				Sensor/ECM	
Platform	F-22 (M)	F-35 (M)	MQ-1C (U)	MQ-9 (U)	EA-18G (M)	RQ-4 (U)
Unit Cost ($M)	186	91	26.5	6.5	70	103
Flight Hour Cost ($K)	11.5	25	-	3.25	25	31
(M) – manned platform, (U) – unmanned platform						

A comparison of the costs of aerial vehicles shows an especially large variance between the unit cost. Both the MQ-1C Gray Eagle and MQ-9 Reaper are used specifically for combat, like the F-22 Raptor and F-35 Lightning II. The F-22 and F-35 may be equipped with an ECM system. Similarly, the MQ-1C Gray Eagle and MQ-9 Reaper have an available ECM payload (Air Force Technology n.d.). When comparing the UAVs to the manned combat vehicles, the conclusion becomes clearer. The average unit cost of the two conventional manned aircraft is $132M. Conversely, the two combat-capable UAVs average $19M per unit. The RQ-4 Global Hawk is primarily used for its reconnaissance capabilities which makes it a great selection for the sensor-enabled UAV. On a similar note, the EA-18G Growler is strictly purposed for electronic warfare, surveillance, and reconnaissance. Evaluated strictly on cost, the UAV option is less favorable. Although the RQ-4 Global Hawk exceeds the EA-18G Growler in unit cost, O&S cost, and flight-hour costs, its deployment eliminates the risk of service member casualties.

Reflecting on Chapter IV, the foundation provided by previous chapters allowed for the modeling and simulation of the OTH mission execution by the UAV swarm. The

1891 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

follow-on analyses found consensus in that OTH mission success is most affected by weapon stores (A/A and strike munitions). Also, the comparative cost analysis for manned versus unmanned platforms found the unmanned platform alternatives to be less costly, save for the ECM function, while eliminating the risk to service members that would otherwise be fulfilling platform role. Moving into Chapter V, the findings of this project will be further discussed with the contributions and potential application benefits identified. The chapter will conclude with a look towards future work that would aid in the further development of the BREM project.

1893 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

V. FINDINGS AND FUTURE WORK

A. FINDINGS

The team used a modified system engineering approach to study the operational utility of adding a swarm of UAVs for the OTH mission. The approach was based on the traditional systems engineering "vee" with a focus on the development of a CONOPs and system architecture, and modeling and simulation (M&S) analysis. The team developed the SSM and ran scenarios to conduct three sets of analyses. The analyses centered on the execution of the OTH mission and included a UAV performance analysis, a swarm size analysis, and a swarm configuration analysis.

The CONOPs development process identified specific UAV configurations for use in the swarm. The process also captured the functional description of the UAV configurations and related the performance of the respective UAV platform as a member of the swarm. The CONOPs itself described the basics of swarm configuration as it relates to executing the OTH mission. The CONOPs also began the development of the BREM swarm mission definitions and the OTH mission scenarios.

The architecting processes that followed the CONOPS development further matured the CONOPs by establishing the system of systems definitions for the BREM swarm. The team produced a series of operational and system views that identified UAV configuration data and communications needs. The architecture aided in describing the need for support assets in the execution of the BREM swarm mission.

The team conducted an M&S effort as a quantitative approach for assessing swarm success during the execution of the OTH strike scenario. The SSM, developed in Microsoft Excel, took a probabilistic approach to capture and evaluate the OTH strike scenario. The SSS used a similar approach to scenario execution but added fidelity to the weapon engagements and was developed in ExtendSim9. The scenario utilized in the M&S effort was developed using the information captured in the CONOPs. The quantitative approach of the M&S effort established performance metrics for the various UAV configurations. The effort also allowed for the capture of swarm size and configuration on OTH mission

1894 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

success. To this end, mission success was evaluated using the probability the swarm would kill the OTH target contrasted against the probability of a loss of a swarm UAV.

A DOE was developed for the UAV performance using the M&S metrics and analysis was completed using the SSM. The results from each of the DOEs were evaluated for main effects drivers. In the UAV performance modeling analysis, the strike loadout was identified as the driving parameter for the OTH hit probability. The analysis also revealed the A/A loadout to be the main driver of the probability that an incoming threat would hit a UAV. The swarm performance assessment was repeated using the SSS with comparable results.

The swarm size assessment and configuration analysis used a standard set of UAV performance values. A DOE was developed for the swarm size assessment and completed using the SSM. The analysis found the strike UAV configuration to be the critical UAV platform for the successful engagement of the OTH target. In addition, loss of the strike UAV was most detrimental to the success of the OTH strike mission. Successive runs of the SSM were completed to obtain the data used in swarm configuration analysis. The swarm configuration analysis provided the probability of an OTH kill as well as the probability of UAV loss for the various configurations. The team produced a table of recommended swarm configurations that depend on the number of red force return fire weapons. When the red force return fire loadout is known, the look-up table (contained in Table 9) shows the minimum number and type of UAV swarm that produces a high probability of success and a low probability of being hit.

The cost analysis for utilizing current UAV technology in the execution of the OTH mission showed that a swarm implementation would likely increase the cost. However, two factors could drive the decision in favor of the use of a UAV swarm for OTH missions. The first is that delivering more UAVs in more mission areas will reduce the unit cost. The second is that as the UAV technology matures with the higher demand, the cost of delivering UAVs will be reduced. These factors, in addition to the casualty risk associated with OTH mission execution, push the decision in favor of utilizing UAVs.

1895 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

B. CONTRIBUTIONS

The modified systems approach completed during this capstone project produced several contributions to the BREM system. The project developed a CONOPs and architecture for the OTH mission that can be utilized in the pursuit of enabling swarm mission capability. In addition, the usable swarm configuration could be used as a lookup table by surface ship combat systems for the execution of the BREM swarm missions. The results of the M&S effort can aid in developing further analyses to unlock new capabilities to be implemented in the OTH mission. The method, data, and tools established by this project could be leveraged to develop similar analyses of existing naval capabilities.

C. POTENTIAL BENEFITS

A practical and near-term benefit of the study will be an Excel application and ExtendSim model to support BREM development and to be used for this project's analysis as well as future analyses. The Excel application will have an interface in which the user may input information regarding the UAVs, coordinates, weaponry, and opposing forces. The application is expected to output the strategic positioning and predictive engagement strategy. The ExtendSim program is expected to mirror the results of the Excel application and provide graphs and visuals to help illustrate.

The results of the project's analysis will provide recommendations and lessons-learned for implementing the addition of UAVs into the BREM automated mission planning decision aid. The M&S of a variety of UAV combinations and configurations for OTH missions will provide an understanding of the operational utility of UAVs for this mission domain. The analysis results will inform the stakeholders of the benefits of integrating the UAVs to the existing BREM gaming system. The stakeholders may also leverage the project towards further development of, and insight into, the BREM functionality as well as UAV capability.

UAV system developers at the forefront of the BREM project will benefit greatly from the project. The results of this study will support the autonomous decision-making component of BREM by adding the potential operational utility of UAVs to the OTH mission. The objective of BREM is consistently to stay in the optimal battle condition of

1896 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the matrix, leading to the highest probability of battle success. With the addition of UAV capabilities and strategies, the BREM will have the potential to achieve even more significant improvements in battle-readiness for OTH missions.

D. FUTURE WORK

The team recommends the swarm size and configuration modeling analysis be repeated using real-world data for UAV effectiveness and reliability. For a baseline, the UAV probabilities could be given F/A-18 performance metrics for similar missions as it is equipped with a sensor package that is similar in concept to the sensor-enabled UAV. In addition, the F/A-18 also features an escort jamming capability that matches the ECM UAV functionality. Lastly, the F/A-18 load outs could be leveraged for the A/A and strike mission package probabilities. By using the F/A-18 data, a better-informed analysis could be completed for the mission effectiveness of the BREM swarm UAVs. The use of measured or predicted values for known UAV reliability could also increase the fidelity of the modeling analysis.

The team also recommends the OTH mission, as completed by manned platforms, should be analyzed to establish a comparative baseline. The data provided by the baseline analysis would allow for a comparative analysis between manned and unmanned assets. In addition, an analysis of manned and unmanned platforms may yield a higher mission probability than either platform on its own.

Further work could be directed towards evaluating the impact of changing the UAV targeting priority during the execution of the OTH scenario. For instance, the ECM and sensor-enabled UAVs could effectively remain outside the OTH engagement range if the ECM UAV supported the swarm as a stand-off jammer with the sensor-enabled UAV acting as a loitering sensor. Removing two UAVs from the engagement area would concentrate on inbound threats, which may increase the probability of successful interception by the A/A weapons. The resulting changes to the OTH targeting methodology would likely necessitate the iteration of the UAV performance drivers and swarm size analyses.

1897 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Another area of development would be enhancing the OTH scenario to reflect a dynamic environment. The addition of swarm UAV countermeasures, environmental factors, and OTH target capabilities would add a layer of fidelity to the SSM. The inclusion of swarm countermeasures would further enhance UAV survivability. Environmental factors affecting UAV and weapon performance would provide insight into optimal swarm configurations for varying environmental conditions of real-world scenarios. Predicting and acknowledging the capabilities of the OTH target are vital to reflect the complex environment accurately in which the strike weapons must operate. Each of these factors necessitates iteration of the UAV performance drivers and swarm size analyses to enable a more versatile swarm configuration.

Further engagement cost analysis would prove beneficial. Dependent on the acceptable level of risk, it would be advantageous to know which UAV configuration yields the greatest probability of success at the lowest cost. This information would provide engagement decision makers with the best cost-benefit analysis. In turn, this would support the allocation of defense spending towards the areas that have the greatest impact on OTH engagement success probability.

13. ABSTRACT (maximum 200 words)

Autonomous and semi-autonomous systems operate on a system of systems (SoS) framework, utilizing their own ability to sense, perceive, analyze, and execute actions to achieve their goals. Unmanned systems present a significant challenge for the Department of Defense's (DoD) acquisition process that was established to develop and field man-in-the-loop type capabilities. The purpose of our thesis is to perform an analysis on the challenges of developing semi-autonomous and autonomous systems through the military acquisition process in order to determine best practices and trends necessary to increase the likelihood of program success.

The secondary goal of our analysis is to compare and contrast Test & Evaluation methodologies for systems with autonomous capabilities. The purpose of the test and evaluation process is to enable decision makers to manage technical risk and assess how robust and mature capabilities are prior to making a fielding decision. Autonomous systems require a rigorous test/build strategy that for most programs lead to cost overruns and schedule breaches. In addition, trying to keep pace with rapidly changing technologies outpaces the DoD's ability to field mature systems with cutting-edge technology.

ACKNOWLEDGMENTS

We would like to acknowledge everyone who has helped us create and evolve this thesis into the final document is has become. It seems like we started this paper with the best intentions to get it completed quickly, and on time, but this Joint Applied Project (JAP) took on a life of its own and quickly grew in scope. We would like to thank our significant others, who provided us with the time to work on this within our busy schedules, and our families, who supported us during the times we struggled to make significant progress. We would also like to thank our advisors, and the Graduate Writing Center coaches, who tirelessly provided input on making this a better product, especially in the weeks prior to our JAP final submission. This report is the summation of everything we have learned during our two years of Naval Postgraduate School (NPS) and everyone that has influenced us in our lives.

Thank you.

I. INTRODUCTION

Autonomous systems have gained tremendous interest and traction within the Department of Defense (DOD) over the past five years. The problem is as technology matures, the need to integrate autonomous capabilities and weapon systems becomes more of a requirement for the DOD. We will attempt to show through case studies, how the DOD is looking to develop a next generation autonomous systems capable of dominating near-peer threats. The DOD's acquisition process for autonomous systems or any other technically complex weapon system can be highly complex, and the implementation costly. As the DOD's interest for autonomous systems increases, it must take into consideration future capabilities and operational training techniques of autonomous systems. According to Parson and Ahner (2016) future capabilities of autonomous systems consist of augmenting human decisions, teaming with humans in the execution of missions, teaming with other systems for collaborative autonomous functions, and extending intelligence surveillance and reconnaissance (ISR). In the same report Parson and Ahner (2016) propose that these future capabilities will be operated in hostile environments. DOD will gain a multitude of new capabilities by implementing autonomous systems out in the field, but with the new capabilities come new challenges.

A. THE ROLE OF T&E WITHIN THE DEFENSE ACQUISITION PROCESS

According to the Parson and Ahner study (2016), the early stages of the DOD adaptation of autonomous systems have provided new challenges in conducting a proper developmental and operational test and evaluation (T&E) process. The challenges include development of requirements, the need for test infrastructure and personnel, autonomous systems test adequacy, need for safety/cybersecurity, and post-acceptance testing of autonomous systems. Figure 1 shows how these challenges line-up within the standard defense acquisition management system framework.

1921 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

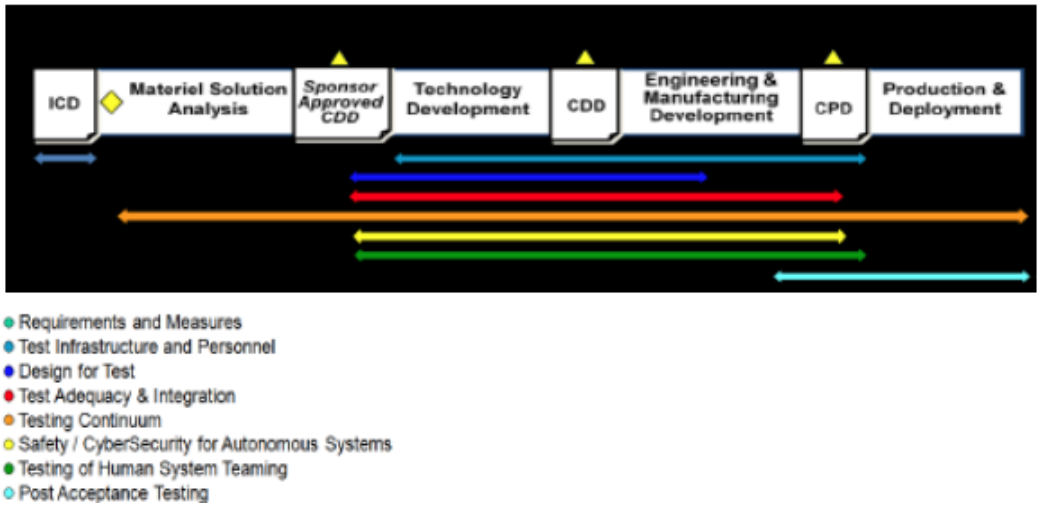

Figure 1. DOD Acquisition Life Cycle Program.
Source: Parson and Ahner (2016).

As more warfighting systems adopt autonomous systems and semi-autonomous systems, the DOD's main goal is to utilize T&E acquisition process to manage technical risks and ensure maturity of requirements are considered before final decision within the acquisition process. As technology matures the DOD and industry communities must keep pace and adapt the changes in technology to the warfighter.

B. DEFINING AUTONOMY

The *Role of Autonomy in DOD Systems* by the Defense Science Board (2012) (hereafter called *Autonomy Report)* defines an autonomous system as a system that is self-governing, with the capability for the operator to control the system without human interactions. When most people think about autonomous system, they think of software taking the place of a human interaction. Autonomous systems do not replace a human being, but rather extend an operator's effectiveness in a multitude of possibilities. The DOD indicates that the main function of autonomous systems is to reduce the cognitive burden placed on warfighter while maximizing effectiveness of any given capability. By adding autonomous systems, the *Autonomy Report* by the Defense Science Board (2012) states that the warfighter can use a DOD system or sub-system more effectively by integrating different requirements between multiple unmanned systems and software-dependent devices, thus allowing more focus on the complex decision-making process. Per

1922 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the *Autonomy Report* by the Defense Science Board (2012) report the warfighter would gain added advantages by utilizing autonomous systems capabilities. Almost all the DOD deployed forces have been eager to use autonomous systems, particularly to counter the threat in compromised areas.

According to a 2009 report by Zilberstein, autonomous systems offer a reframing effect on society as they help decrease human workload and achieve productivity and safety. The same 2009 report, Zilberstein highlight that autonomous systems have been in operation in a great variation of forms, from special types of vacuum cleaners to space exploration vehicles. Ironically, there is no specific definition of autonomy in artificial intelligence (AI), but if a system can build and carry out a plan that achieves an assigned goal without human intervention it is considered autonomous.

The DOD sees the need for full autonomy but has incrementally implemented autonomy through semi-autonomous systems as a more feasible goal. The Zilberstein (2009) report defines semi-autonomous systems as a system that can operate autonomously under certain conditions but may require some human interactions in order to achieve its final goal.

For semi-autonomous systems to be successful, three technical approaches reported in the Zilberstein 2009 report must be considered. First, a human operator should have high competence to observe or interact with the current state of the process. Second, a human operator must have the ability to perform actions that are not available to the semi-autonomous systems (e.g., climb stairs). Third, a human operator must demonstrate a different level of competence in performing various tasks depending on certain actions (e.g., removing a stuck light bulb without breaking it) within the DOD T&E process.

C. THE IMPORTANCE OF AUTONOMOUS SYSTEMS ON THE BATTLEFIELD

In the future, autonomous systems will give warfighters numerous enhancements such as: augmenting human decision-making, teaming with humans in the execution of missions, teaming with other systems for collaborative autonomous functions, and extending situational awareness. These enhancements will allow the warfighter to operate

1923 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

a system that has a set of high-level capabilities that allow the warfighter to reply to a set of circumstances that were not pre-programmed prior to system deployment.

In addition, these enhancements will provide systems with the ability to operate in any environment without the need to preprogram software within specific boundaries, due to the artificial intelligence being able to adapt to its environment. By giving the warfighter autonomous systems capability, the number of warfighters on the battlefield will decrease, and the efficacy of each warfighter will be greater. The DOD systems that are autonomous systems or semi-autonomous systems enabled, will allow the warfighter to combat in areas not accessible in the past. As a result, we opine that the more the DOD adopts autonomous systems the less causalities will occur.

The DOD has the operational need to increase autonomous systems across air, sea and ground applications. As DOD adopts autonomy, DOD must maintain and improve a systemic approach for T&E and account for the mission needs for present and future operational environments. For industry to account for DOD mission needs, it first must understand how DOD intends to use autonomous systems.

Our plan for this JAP is to analyze test documentation, engineering reports and scientific studies to answer the research questions to follow, specifically focusing on T&E data extrapolated during the technical maturation and risk reduction phase, the engineering and maturing phase (EMD) and production and deployment phases.

The purpose of this analysis is to: 1) identify the shortcomings within the T&E methodology in comparison with industry best practices; and 2) determine corrective actions that can transition to the organic T&E test agencies in the hopes of increasing the chance of fielding autonomous systems to the warfighter. We use the case studies demonstrated in the later part of this JAP to analyze the challenges these systems face and broadly extend lessons learned from these case studies to the development of all autonomous capabilities.

In addition, we show how best practices and commercial trends can be transitioned from industry to DOD's T&E methodology. At the end of our JAP we determine if the

1924 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

current DOD T&E process or industry's T&E processes provide a better evaluation of autonomous systems by answering the following primary and secondary questions:

(1) Primary:

- What unique challenges are presented by autonomous systems to the DOD T&E and industry communities?

(2) Secondary:

- Does the DOD have the correct resources to conduct tests and evaluations of autonomous systems?

In this chapter we introduced autonomous systems, explained the role of T&E within the defense acquisition process, defined autonomy, and discussed the future importance of autonomous systems on the battlefield. As the DOD begins to adopt autonomous and semi-autonomous systems, so does industry. The following chapter provides additional information on the background of autonomy based on DOD's vision, several implementations of autonomy in current day programs and a summarization of their T&E phase as compared to the industry standard. The maturity of autonomous systems and semi-autonomous systems will cause DOD and industry communities to evaluate the challenges they will have to meet, and how to best allocate resources to conduct T&E of autonomous systems.

II. BACKGROUND

A. DOD VISION FOR AUTONOMOUS SYSTEMS IN THE BATTLEFIELD

Beginning in 2011, the DOD published a series of Unmanned Systems Integrated Roadmaps, laying out a vision for future military technology investment, which covered advancements in sensors, communication, power, weapons, propulsion and other key enablers for future autonomous systems. The purpose of these roadmaps was to provide a reference for defense acquisition leadership to pursue science and technology initiatives that align with the overall DOD strategic guidance. The 2011 roadmap presented key technological areas that represented DOD's specific interest in artificial intelligence and machine learning, which are the key enablers for future autonomous innovations and machine human collaboration (see Figure 2).

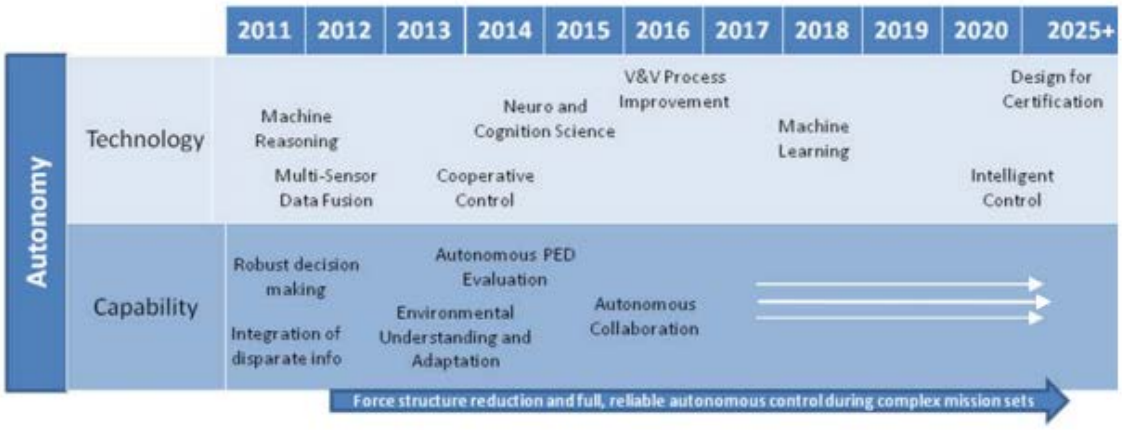

Figure 2. Defense Science Board's 2012 Autonomy Roadmap. Source: Defense Science Board (2012).

The DOD's vision behind the 2011 roadmap provides insight into the military's gamble with autonomy and the heavy reliance on artificial intelligence in future warfare (Defense Science Board, 2012).

> For unmanned systems to fully realize their potential, they must be able to achieve a highly autonomous state of behavior and be able to interact with their surroundings. This advancement will require an ability to understand

1927 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

> and adapt to their environment, and an ability to collaborate with other autonomous systems. (Scharre, 2018)

This excerpt from (Scharre, 2018) provides context to how the DOD is positioning autonomous systems in the future fight and how the military is planning to achieve overmatch against near-peer threats. Based on the current dominance of drone strikes utilized in the war on terror in the Middle East, future threats will focus on the ability to contest remotely operated systems such as drones and robotic platforms on the battlefield, rendering these capabilities useless. One option the military is planning to utilize to mitigate this is emphasizing higher levels of autonomy for the purpose of developing systems that can operate independently without the need of manned teams facilitating functionality. Additionally, the military is conducting research on drone swarm technology, which is capable of controlling hundreds of "mini-drones" required to overcome enemy threats. DOD is betting on a future of AI and unmanned systems seamlessly coordinated with manned teams influencing and dominating the battle space. AI capable of identifying threats at longer range, providing intel to ground forces and coordinating activities between unmanned and manned forces. These capabilities will enhance the military's capability in the future by reducing the warfighter's cognitive and physical load, while providing a means to improve lethality on the battlefield.

B. DOD KEY ENABLING TECHNOLOGIES FOR AUTONOMOUS SYSTEMS

The DOD *Autonomy Report* (2012) identifies six areas in artificial intelligence that have made significant improvements for autonomy: "perception, planning, learning, human-robot interaction [HRI], natural language understanding, and multi-agent coordination" (p. 31).

The report also describes how perception is key to autonomy and enables the autonomous systems to reach mission objectives. Per the DOD *Autonomy Report* (2012) perception includes sensors (hardware) and sensing (software). The hardware (sensors) includes raw inputs to sound, pressure, temperature, and lights. The DOD *Autonomy Report* (2012) explains how "perception for mission sensing is needed for mission planning,

1928 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

offering four significant benefits"(pg. 42). Planning is the steps related to how a sequence is computed or partial order of actions that changes from present circumstances to a desired circumstances. In the same report, the planning process consists of two components. The first component represents human actions, and description of world objectives and resource optimization criteria. The second component represents how the DOD learns to design software algorithms that will compute actions in sequences and assign the appropriate actions to conform the hard constraints of the problem, while optimizing the soft constraints. According to the DOD *Autonomy Report* (2012) machine learning is considered the most critical aspect of advancing intelligent autonomous systems.

The DOD *Autonomy Report* (2012*)* states HRI is new to autonomous systems. The same report defines HRI as an integrative field that interact direct human interaction compared to current usage of robots versus computers or tools. The DOD *Autonomy Report* (2012) further states that,

> HRI is a group of a bigger field that focuses on bi-directional, cognitive interactions in which the robot is a physically situated agent operating at a distance from the user, versus a computer or autopilot, thus leading to significant distinctions. (Defense Science Board, 2012)

In the same report the DOD benefits from HRI by improving performance of existing platforms, which will reduce cost for new situations.

Natural language is defined in the DOD *Autonomy Report* as the most inherent way for the user to control autonomous systems. Natural language understanding grants for a more diverse, superior operation rather than and more detailed teleoperation. As revealed in the DOD *Autonomy Report*, multi-agent coordination is applied to accomplishing a designed task for software or humans. The DOD *Autonomy Report* states that,

> Each multi-agent component is considered to have some degree of individual autonomy and the coordination may either emerge from the agents interacting or negotiating with each other directly (distributed coordination) or be explicitly directed by a planner (centralized coordination). (Defense Science Board, 2012)

In the next section, we present a brief overview of the four DOD programs of record (PORs) that we chose to analyze in this JAP. Each of the programs demonstrates one or

1929 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

multiple areas of autonomy designated by the Defense Science Board and were fully funded efforts that required a formal T&E process by the Army Evaluation Center. Each of the four PORs have a semi-autonomous systems capability that required an integrated project team (IPT) to develop non-traditional T&E methodology to verify and validate the autonomous functionality. In the next section we provide a brief synopsis of each program's development history and the implementation of their autonomous functionality.

C. DOD PROGRAMS OF RECORD WITH AUTONOMOUS FUNCTIONALITY

1. Gray Eagle

According to the *Selected Acquisition Report* (SAR) (2010) Gray Eagle or MQ-1C Unmanned Aircraft System (UAS) program is the Army's primary aerial system capable of providing reconnaissance, surveillance, security, attack and command/control missions' types for the joint force units. Gray Eagle Quick Reaction Capability (QRC) 2 Units are capable of autonomous takeoff and landing, employing hellfire missiles and tactical landings (SAR 2010). All other functionality is coordinated by an operator within a ground control station.

The SAR (2010) states that the Gray Eagle was initiated in April 2005 at milestone (MS) B and began as an acquisition category (ACAT) II program planned to replace the Hunter UAS, in response to secretary of defense requested to increase support in Iraq and Afghanistan. The SAR (2010) reports that the initial program was approved for procurement of four systems and associated equipment, but was increased to 12 systems post MS B.

The SAR (2010) states by the spring of 2008, the secretary of defense managed the deployment of prototype Gray Eagle UAS equipment to support the war in Iraq. QRC Gray Eagle systems were procured and deployed to support Operation Iraqi Freedom and Operation Enduring Freedom. Based on operational mission duration taken from both accounts, the deployed systems were capable in excess of 10,000 flight hours with zero accidents. In May of 2008, Gray Eagle was re-designated as an ACAT 1D and by March of 2010 approved for a MS C. The MS C was later rescinded and changed to March 2011

1930 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

based upon recommendation from the vice chief of staff of the Army convening a configuration steering board. Adjustments increased the allowable Gray Eagles within a platoon to 3 per company, which was a total increase from 12 to 17 Gray Eagle UAS companies. According to the SAR report PM-UAS performed a successful limited user test (LUT) in the third quarter FY 2010 and initial operational test and evaluation (IOT&E) was completed in the first Quarter FY 2012. Figure 3 is an image of a MQ-1C UAS Gray Eagle.

Figure 3. Selected Acquisition Report: MQ-1C UAS Gray Eagle. Source: SAR (2010).

2. Autonomous Mobility Applique System (AMAS)

According to the AMAS system overview, the AMAS is an Army initiative providing a low-cost/low-risk solution to retrofit an autonomous driving capability onto existing military tactical wheeled vehicles. AMAS offers driver warning/driver assist performance, leader-follower vehicles for protection operations, and waypoint following

1931 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

efficiency. The AMAS kit is composed of a three-part system of environment sensor, actuators that move the vehicle and pump the breaks and central computer that processes the sensor data and commands the drive system.

Based on the AMAS system overview, in the summer of 2014, the engineers at Tank Automotive Research, Development and Engineering Center (TARDEC) demonstrated the AMAS system at Savannah River site, in Aiken, South Carolina. The demo consisted of several types of vehicles being autonomously driven in operationally realistic scenarios. The assessment resulted in a positive recommendation to continue development. Additional progress was made in 2015 again when the driver warning/assist capability was successfully tested with soldiers. The demonstration was set up to test the collision mitigation braking, adaptive cruise control and lane keeping capability of vehicles equipped with the AMAS technology. The primary and secondary safety systems of the AMAS were successfully demonstrated, establishing AMAS's capability to reduce equipment loss and mitigate potential accidents.

In addition, the AMAS system was successfully demoed during the U.S. Army Extended Warfighter Experiment at Fort Leonard Wood, Missouri, and Fort Bliss, Texas. The EWE is a U.S. army training and doctrine command sponsored event, managed by the U.S. Army TARDEC. The event was significant for both Lockheed Martin (the initial system developer) and TARDEC as they successfully logged 55,000 miles on the system and received a recommendation to move to widespread fielding across multiple military applications. The Figure 4 is an image of an AMAS system.

1932 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 4. Autonomous Mobility Applique System Overview. Source: Lockheed Martin (2018).

3. Project Perdix

According to the Strategic Capabilities Office (SCO) (2011), Project Perdix is the name of a MIT Lincoln Laboratory initiative to use a group of micro-drones (mini unmanned aerial vehicles) for ISR missions. Project Perdix was successfully demonstrated by the SCO, in September 2014, for the DOD at the Air Force Test Pilot School, Edwards Air Force Base. The test utilized an F-16 flare canister as a transportation/ejection method and was successfully capable of launching a swarm of autonomous drones without damaging any of the drones. Over the next two years the program would transition to the SCO, Naval Air Systems command, where the military alongside MIT, demonstrated a swarm of 103 Perdix drones being deployed from an F/A-18 Super Hornet. The SCO revealed the demonstration is considered a milestone in drone swarm technology and demonstrated advanced behavior “such as collective decision-making, adaptive formation, flying, and self-healing”(pg.1). The Perdix drones can share a single collective mind for decision making and adapting to each other and the different environmental factors. The

1933 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Perdix drones will provide the military the capability to allow a swarm of inexpensive drones to perform missions, disrupt communications and track targets of interest. The Figure 5 is an image of a single Perdix drone.

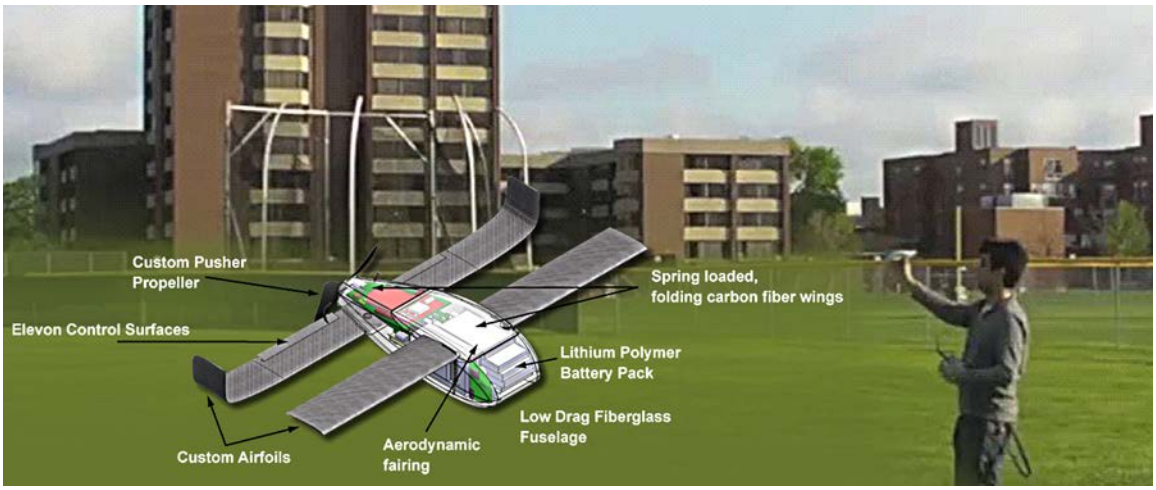

Figure 5. Project Perdix. Source: Hansman (2011).

4. Stand-off Robotic Explosive Hazard Detection-Neutralization (SREHD)

SREHD is an Acquisition Category III (ACAT III) program developed as a capability to detect, mark, and neutralize explosive hazards (EH) (e.g., landmines, improvised explosive devices, booby-traps, and unexploded explosive ordnance) in either complicated or underground environments. SREHD is capable of being mounted on unmanned ground vehicles platforms organic engineering unit.

In 2002 the Army Technology Objective initiated an effort to develop a concept to autonomously detect explosive hazards on the battlefield. Concept Phase 1 was conducted as a market survey for technology approaches to autonomous mine detection of anti-personnel and anti-tank landmines from a small surrogate robotic platform. Concept Phase 2 was a prototype design evaluation to determine the probability to detect and coverage rate autonomous capabilities against realistic threats in varying environmental conditions. SREHD formerly known as the Autonomous Mine Detection System was developed by two competitive, state-of-the-art sensor packages developed for handheld, man portable

1934 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

detection systems. CyTerra Corporation leveraged technology from the Army/Navy Portable Special Search 14 Mine Detecting Set and NIITEK Inc. was able to leverage ground penetration radar to meet the required objective. Both contractors were awarded contracts to explore technology approaches capable of autonomously detecting landmine. Concept Phase 3 was developed and assessed prototypes against mission scenarios in relevant environments. At the culmination of Phase 3, the Program Management office for Close Combat Systems awarded a contract to Carnegie Robotics Limited (CRL) for their Dismounted Standoff Explosive Hazard Detection, Marking and Neutralization approach. On 30 April 2018, PEO Ammo as the SREHD Milestone Decision Authority successfully approved a MS C decision and CRL was award an additional option to produce 16 units in support of low rate initial production (LRIP) (Test and Evaluation Master Plan, SREHD, 2018). The Figure 6 is an image of a SREHD system.

III. ANALYSIS OF TEST & EVALUATION METHODOLOGIES

A. THE IMPORTANCE T&E FOR AUTONOMOUS SYSTEMS

The DOD has not developed any specific guidance for T&E of autonomous systems. Currently, autonomous systems are tested and evaluated under the same methodology as any other complex weapon system. The process starts by decomposing requirements into their basic operational intentions. Test plans are created and approved by system stakeholders, test leads evaluate system performance by executing a series of repeatable system tasks for the purpose of evaluating and verifying predictable system operational requirements.

The DOD *Autonomy Report* (2012) describes the current state of DOD's test and evaluation challenges and recommendations for T&E of autonomous systems by stating,

> Traditional test programs have been focused on repeatable performance testing, measuring a response and comparing that response to a documented performance specification. Testing perspectives need to shift to a view that is more broadly mission based and assesses the ability of the autonomous system to meet mission goals. The framework employed for testing must provide leeway to the system to adapt plans to achieve mission goals in a variety of ways that cannot necessarily be predetermined. The fact that the system's software reacts to external stimuli and makes non-scripted, but bounded, decision is particularly challenging to the test community that is more accustomed to executing testing in a fully scripted sense. The ability of the T&E community to react to this changing paradigm is limited by the understanding of how autonomous systems truly make decisions. Additionally, the DOD T&E workforce must be enhanced with new skills for robotics, artificial intelligence, networking and systems engineering for autonomous systems. (Defense Science Board, 2012)

This excerpt clearly defines the critical need for a T&E community tailored to the nuances of measuring the effectiveness and suitability of autonomous systems.

B. THE COST OF TEST & EVALUATION FOR AUTONOMOUS SYSTEMS

Autonomous systems operate on a system of systems (SoS) basis. Fundamentally, this means that a collection of resources and capabilities work together to create a more complex and enhanced capability, which offers more functionality and performance than

1937 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the sum of its individual components. The increased amount of functionality can lead to emergent behavior that can be a challenge to the T&E community to replicate, verify and validate. The government's current verification and validation methodology ensures user requirements are evaluated based upon a predictable and expected performance envelope. The T&E community then collects, assesses and judges whether the performance measures fulfill requirements. This data collection period begins during the technical maturation and risk reduction phase and typically ends during the end of the EMD phase. The purpose of T&E within the Defense Acquisition process is to help decision makers assess the maturity of a capability and reduce the risk of failure to the system owner and users. The systems approach to test and evaluation is the principal means of demonstrating a program's readiness for deployment.

SoS T&E requires broad-scale resources based upon the complexity of the systems, missions and conditions the warfighter expects to utilize the capability. System engineers work with the T&E community to break down requirements, systems and missions into smaller pieces, which are translated into quantifiable measures. Large, exhaustive and costly experiments are conducted to inform development integrated product teams (IPT) and other system stakeholders of the overall maturity of a system and its relative timeframe to fielding.

As an example, Gray Eagle is a major defense acquisition program (MDAP) that was required to undergo IOT&E to validate its autonomous functionality. Gray Eagle's autonomous functionality includes a system capable of automatic take-off and landing (ATL) as well as a system capable of employing Hellfire missiles on a verified threat.

The information that was gathered in Table 1 and Table2, includes Gray Eagle's acquisition program baseline (APB) and the project management office (PMO) budget to fund autonomous requirements in IOT&E from September 2011 and August 2012. Using information gathered in Table 1 and Table 2, which includes Gray Eagle's acquisition program baseline (APB) and the project management office (PMO) budget to fund IOT&E from September 2011 to August 2012. We can use the established timeline in Table 1 with Gray Eagle's annual funding in Table 2 and surmise how much money was spent to validate the autonomous functionality.

1938 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 1. MQ-1C Gray Eagle's Schedule. Adapted from SAR (2010) and SAR (2007).

Schedule Events				
Events	**SAR Baseline Production Estimate**	**Current APB Production Objective/Threshold**		**Current Estimate**
Milestone B	Apr 2005	Apr 2005	Apr 2005	Apr 2005
SDD (EMD) Contract Award	Apr 2005	Apr 2005	Apr 2005	Apr 2005
Critical Design Review	Feb 2006	Feb 2006	Feb 2006	Feb 2006
Milestone C	Mar 2011	Mar 2011	Mar 2011	Mar 2011
IOT&E				
IOT&E Start	Sep 2011	Jul 2012	Jul 2012	Jul 2012
IOT&E Complete	Oct 2011	Aug 2012	Aug 2012	Aug 2012
IOC	Jun 2012	Dec 2012	Dec 2012	Dec 2012
FRP Decision	Apr 2012	Jul 2013	Jul 2013	Jun 2013
FOT&E I	Aug 2012	May 2015	Nov 2015	Jun 2015
FOT&E II	May 2013	N/A	N/A	N/A

Prior to the ATL being implemented on production units, General Atomics was required to verify Gray Eagle's ability to autonomously take-off and land to ensure the safety of military test assets and a successful IOT&E. Additionally, information was gathered through a press release by General Atomics, establishing the system demonstrated 20,000 successful take-off and landings on various runways around the world (General Atomics, 2012). The (PMO's) schedule of events published in the MQ-1C Gray Eagle 2016 SAR (Table 1), confirmed Gray Eagle's IOTE was scheduled to begin in September of 2011 and ended in August of 2012. Execution of all these events required prior year planning to include the acquisition of test hardware, verification of system performance, maintenance/logistic documentation and trained operators for system demonstration before the beginning of testing in September of 2011. This schedule of events coincided with a peak operating test budget between the years of 2010 to 2012 which reflects the highest development cost during Gray Eagle's engineering maturation phase as shown in Table 2 SAR (2007).

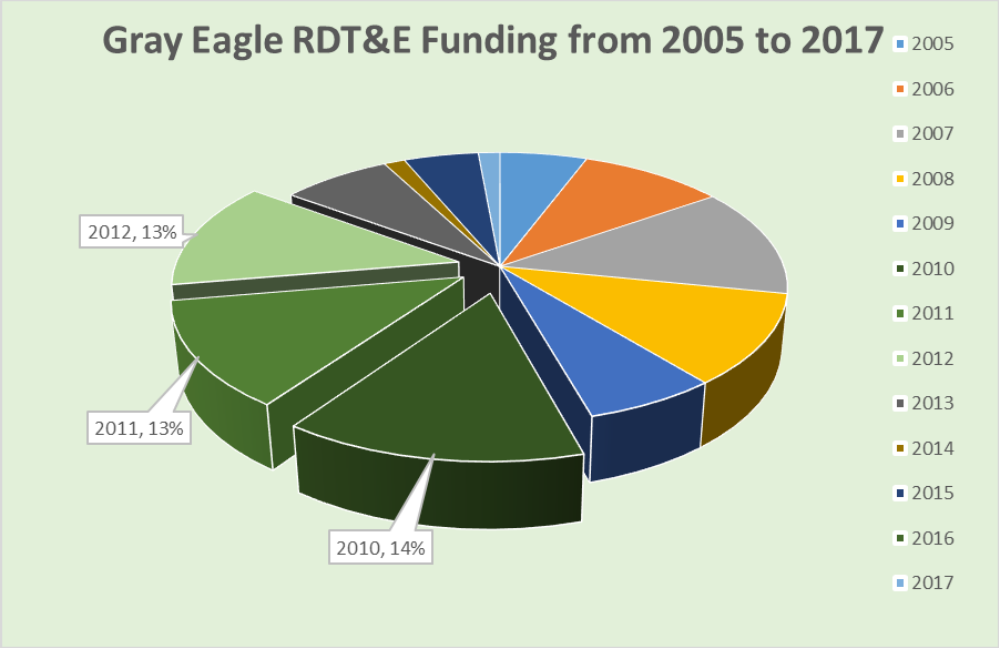

Figure 7. Gray Eagle RDT&E Funding. Adapted from SAR (2010).

1940 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Based on the data provided, the Gray Eagle program spent the largest amount of RDT&E funds during the same period of the time in which they were verifying the system's automatic takeoff and landing capability. A one-to-one correlation to Gray Eagle's budget and IOT&E cannot be discerned from just the information researched for this JAP. There are most likely several other major factors that affect the overall increase in cost. We are assuming that since the majority of testing between 2010 to 2012 was contractor testing of the ATL semi-autonomous system, then the overall cost to verify Gray Eagle's autonomous capability in an operational environment was the cost driver during the end of the EMD phase, as referenced by both the SAR and General Atomics System AUSA announcement, (General Atomics, 2012).

C. DOD TEST & EVALUATION METHODOLOGIES

Throughout this next section, we present the research was conducted on our four (4) DOD programs of record to analyze the T&E techniques utilized throughout their system development.

1. SREHD T&E Test Methodology

SREHD's autonomous capability enables the system to independently detect and mark a broad spectrum of surface-laid and buried explosive hazards and triggering mechanisms in support of route clearance and breaching operations. SREHD is unable to neutralize explosive hazards autonomously, rather the operator is always required to provide the primary and secondary confirmations prior to a neutralization. This is to prevent accidental functioning of the munition during a route clearance mission.

The testing methodology utilized by the SREHD IPT involved various test sites that specialized in specific areas of testing in order to assure the proper standards were followed providing the evaluators the necessary information to assess autonomous performance. Both Yuma Proving Ground in Arizona and AP Hill in Virginia were used to simulate likely threat environments in which a clearance brigade would operate. During the technology demonstration phase, the contractor utilized experimental prototype systems in order to assess SREHD's autonomous surface detection capability and ability to

1941 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

independently maneuver a detection system at precise head height to maintain accuracy of probability of detection model.

Modeling and simulation (M&S) of SREHD's detection algorithm software was also utilized throughout initial development to assess how different external environmental factors could potentially impact the system's performance. This allowed the contractor to quickly evaluate changes and train the system without requiring weeks of probability detection testing.

During the EMD phase, a combination of component, subsystem, and system level testing was utilized to stress SREHD's performance over several hundred hours of testing. Operators were required to simulate a route clearance mission with the entire SREHD operational load and clear a 1.5-meter-wide lane for troops to utilize. Both surface-laid and deep-buried targets were hidden within the "lane" and SREHD was required to autonomously travel the length of the path marking and detecting possible UXOs. Test periods ended with data collectors scoring system aborts and essential function failures and required the engineering team to work with the contractor to develop a corrective action plan that would mitigate the failure and reduce future risk of failure.

2. Gray Eagle T&E Test Methodology

According to the (DOT&E,2010), test team generated thousands of hours of operational flight testing, autonomous takeoff and landing in addition to threat acquisition and threat neutralization test flights (DOT&E, 2010). Testing was conducted at Edwards Air Force Base, California, and the National Training Center (NTC), Fort Irwin, California. To date, Gray Eagle utilized computer-based simulation training for Gray Eagle operators and actual test flight in both the continental United States and outside continental United States environments.

The computer-simulated test environment is primarily used to train Gray Eagle operators with monitoring flight systems, air traffic and communication systems with other forces. In the rare instance a target requires neutralization, operators are required to authorize the use of force prior to threat engagement.

1942 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

During Gray Eagle operational testing, autonomous systems are verified and validated using continuous software checks, flight instrumentation data collection and continuous hour's flight reliability data. Since Gray Eagle is an ACAT 1D program, the low rate initial production (LRIP) quantity was requested and authorized for employment in OCONOS missions for reconnaissance. The system was able to be tested in a constrained and conflicted environment. Operators were able to fully test Gray Eagle's sensors and autonomous capabilities against foreign threats.

3. Project Perdix T&E Methodology

Project Perdix is still pre-MS A as of completion of this JAP, so there hasn't been a formal T&E master plan drafted or approved. Based upon the limited data collected on Project Perdix development, the test methodology has been to evaluate the swarm intelligence of Project Perdix, the swarm's ability to autonomously avoid obstacles and its ability to be launched from an F-16 in flight. Since the primary autonomous capability of the Perdix system is its ability to autonomously navigate low altitudes and independently control individual drones within the swarm, government experiment and testing has primarily focused on increasing the size of the swarm and increasing the complexity of the test environments.

On October 2016, the Navy successfully deployed 103 Perdix drones from three F/A-18 Super Hornets over China Lake, California. Perdix demonstrated quick maneuverability, adaptive flying formations and self-healing.

Typical testing for military-employed small UAV's consists of autonomous target tracking, flight duration and payload delivery. DOD uses White Sands Missile Range, New Mexico and Fort Bliss, Texas as its primary test facilities for new UAV's in development.

4. AMAS T&E Test Methodology

The Army's AMAS or "convoy system" is primarily tested either at Fort Leonard Wood, Missouri, Aberdeen, Maryland and Fort Bliss, Texas. The applique kit has been tested on the M915 line-haul truck, medium tactical vehicle replacement, palletized load

1943 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

system and the heavy equipment transport vehicles. Lockheed Martin has successfully logged more than 55,000 miles using the AMAS capability.

The test methodology for AMAS is primarily roadside simulations of its autonomous adaptive cruise control, assisted breaking and parking, collision avoidance and pedestrian detection. The automotive technology evaluation facility at Aberdeen Proving Ground (APG) can use plastic vehicle targets, Styrofoam mannequin pedestrians and other robotic devices to represent various scenarios to gather system characteristic data and replicate possible safety hazards. Testing is done with little to no human intervention to accurately simulate realistic operational scenarios of the AMAS system and mitigate any possible safety risk to personnel. During test events, data collectors are monitoring the AMAS capability to navigate dense urban environment in a convoy formation, braking and avoiding obstacles and its ability to warn other vehicles in the convoy of sudden changes in terrain. Data collectors measure the accuracy of the AMAS capability to correctly navigate the course based on a predetermined path pre-programed into the system versus how well it navigates the course based on real-life obstacles moving in and out of lanes. The data is then used to create models that eventually will be used to simulate the AMAS capability across different types of courses and reduce future test cost.

The goal of the AMAS test program was to transition into other programs of record for route clearance and interrogation systems. The future of the AMAS system will be fully autonomous vehicles as a counter to roadside hazards explosive operations mitigating the need of a soldier directly in harm's way.

5. DOD T&E Facilities for Autonomous Systems

Currently the military does not have dedicated test facilities positioned for unmanned autonomous systems. The major range and test facility bases (MRTFBs) are the designated core set of T&E infrastructure and associated workforce for the DOD and are preserved as national assets. The common methodology across DOD for testing unmanned systems is to utilize existing facilities and infrastructure used for manned systems.

1944 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Typically unmanned aerial systems are tested in conjunction with the existing Army facilities. The Army's Gray Eagle utilizes Edwards Air Force Base in California and the National Training Center (NTC), Fort Irwin, California.

The SREHD payload is currently tested on route clearance lanes at Yuma Proving Ground in Arizona or in the rougher terrain of Fort AP Hill, Virginia. Test facilities are reconfigured from either existing foot trails or vehicle lanes and repurposed for SREHD payload test events.

The AMAS capability went through verification testing at Fort Leonard Wood, Aberdeen Proving Ground and Fort Bliss during its development. These test sites were originally intended to be vehicle test ranges that again were repurposed as test facilities for an autonomous capability.

6. DOD T&E Software, Simulation and Modeling Strategy for Autonomous Systems

All unmanned systems utilize advance software algorithms as the backbone their functionality and architecture. The DOD has a long running history of software-intensive programs that result in long delays in fielding, significant and cost overruns, as seen in high profile programs like the F-35 joint strike fighter (Maurer, 2019). The system engineering process within the defense acquisition environment has a solid foundation in mechanical-based designs versus software development, even though both contribute an equal measure to system functionality. This has resulted in challenges in both software development and software T&E within acquisition programs. Typical government procurement of software-intensive systems requires heavy industry investment and government oversight and requirement decomposition. Commercial off-the-shelf (COTS) software solutions remodified for government weapon system purposes are the predominant acquisition scenario for DOD software-intensive systems. COTS software solutions reduce the overall government investment cost, and quickly provide a solution mature enough to field.

DOD methodology for T&E of software-intensive systems during development is a controlled, statistically significant and iterative process. Tests are usually designed to verify performance and ensure quality attributes have been satisfied. During development

1945 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

of software-intensive systems, software is the significant driver of system maturity, to include system performance measures. System integration teams are established to iteratively validate and verify software builds prior to release.

The DOD T&E acquisition community defines software maintenance as the, "process of modifying a software system after delivery to correct faults, improve performance or adapt it to a changed environment" (Hamilton, 2017). Testing of software-intensive systems during the sustainment phase of life cycle acquisition involves verifying software systems continue to perform in accordance with requirements.

In addition to software testing, DOD also uses M&S as an additional means to test, analyze or train real world capabilities in controllable environments. The M&S Coordination Office is the DOD's central repository for providing policy to Army, Navy and Air Force Agencies (Defense Modeling & Simulation Coordination Office [DMSCO], 2019). DOD supports using M&S across the entire life cycle of its programs, but it's often used to verify metrics during the EMD life cycle phase. The data gained from simulation is used to provide confidence in design decisions prior to integration and recommendation on a critical path forward. It is DOD policy that only programs that have had their models verified and validated throughout their life cycle by an accredited organization can be used as substitutes for actual test data (Department of the Army, 2014).

D. TEST & EVALUATION METHODOLOGY FOR COMMERCIAL AUTONOMOUS SYSTEMS

Currently there is no overarching policy or industry standard for the commercial sale of autonomous systems. Unlike either the Food and Drug Administration which was stood up to protect and control food safety, tobacco products and over-the counter pharmaceutical drugs or the Federal Communications Commission, which is an agency within the government that regulates interstate communications by radio, television satellite or phone, there currently no federal agency to create, promote or oversee the safety standards for autonomous systems.

Commercial autonomous systems have been in the public sector since the 2004 defense advanced research projects agency (DARPA) challenge, where autonomous

1946 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

vehicles were tested in a series of challenges by the DARPA to self-navigate a 150-mile course in the Mojave Desert region of the United States. This event was key in pushing autonomous vehicle technology forward because the major car manufactures started investing more and more funding into research and design solutions for autonomous capabilities.

This thesis analyzes the autonomous test capability of various industries with commercial autonomous systems in order to compare similar capabilities to the four identified DOD programs. The autonomous vehicle industry, autonomous agriculture systems, and autonomous aerial systems each have their own set of separate standards and testing capabilities that sets them apart from one another.

1. Agriculture System Capability T&E Methodology

The future of agriculture is heavily dependent on producing healthier food, quicker and more efficiently than existing farming techniques of today. Farmers are more reliant on highly skilled personnel to work fields and drive machinery necessary to keep crops thriving, which can be a challenge during peak seasons. Tomorrow's farmers will be driven to utilize more autonomous machinery that will be just as safe if not safer than humans. Autonomous agriculture systems enable farmers to extend their workday to a 24-hour, non-stop operation (Edan et al, 2009, pp.1095-1128).

According to the same report Autonomous Solutions Inc. (ASI) and Case and New Holland (CNH) Industrial are the current market leaders in providing automation technology for the agriculture industry. ASI and CNH provide autonomous tractors that can autonomously seed, plant and till for broad acre and row crop farms. Per the automation agriculture report (Edan et al., 2009), state operators can collect real time data on both the health of crops and maintenance of the machinery. ASI provides the hardware and software solutions that are capable of being retrofitted into existing agricultural systems or integrated into new machines. CNH industries designs, produces and sells agriculture machinery all over the world.

ASI's test methodology, verification and validation of their autonomous agriculture equipment is done on a private proving ground built within their engineering facility (ASI

1947 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

2016). ASI can rapidly prototype, develop and test experimental autonomous equipment on a test farm environment. The test farm is pre-equipped with sensors, cameras and digital measuring equipment that enables ASI to remotely monitor their new equipment and adjust systems in real time to overcome issues and failures. Systems can be run 24/7 within a simulated environment to test maintainability and sustainability of systems prior to commercial release. After equipment is commercially released, new features can be added based on customers' specific needs and problems can be replicated to reduce customer down time. ASI's proving ground also enables them to monitor the stress of high-risk components over time and make design decisions at a higher confidence rate (Scott Garvey 2018).

During early development of CNH's autonomous tractor, ASI oversaw the intensive test program for both the tractor and planter interfaces as the system transitioned unto "real world" testing across four locations in the U.S. and Canada. CNH has partnered with Bolthouse Farms, a major carrot grower and food wholesaler to utilize the autonomous tractor alongside existing equipment. Testing was conducted to evaluate how well autonomous tractors till versus existing manned tractors. Testing has taken place across a variety of tillage applications, soil types, weather conditions and sensing and perception activities. The goal of the "real world" test was to verify that the autonomous tractor can efficiently function in any environment and provide traditional farmers an experience farming in the future with autonomous systems. The Figure 8 is an robotic tractor of the future.

(1) Drone Manufacturer T&E Methodology

Commercial drone manufacturer's T&E methodology of autonomous aerial systems is centered on assuring effective and safe operational performance in response to sudden changes in external environments (Intertek, 2016). Autonomous aerial systems are required to safely fly in fair and extreme weather conditions around the world and make independent decisions regarding the safest course of action.

Based on the severity and expense associated with testing autonomous aerial systems, private industry spends most of its resources utilizing simulation and modeling to verify and validate software systems responsible for independent behavior early in the development phase of new products. Even before metal is cut in the manufacturing of a UAV, software engineers have already verified and validated software models that simulate and correct system behavior. Industry has the capability to heavily rely on reusing

1949 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

much of their existing software code from prior products as software assurance for future products.

This method of software development minimizes the time needed to validate new features while reducing the total amount of resources needed for test and evaluation newer products. This incremental approach to T&E of autonomous software systems has turned into a reliable way of introducing new products to the commercial sector faster with minimal amount of testing required and spending. New products are scaled to work with limited features that have been thoroughly tested and as newer models are released, additional features and increased levels of autonomous behavior are added to all of the existing product lines, adding new features and capabilities. Companies such as Dajing Innovations (DJI) and 3D Robotics have used a single software platform to iterate on various products to the market within a short time frame.

Although the civilian drone market has become a booming sector for new startup businesses, BI Intelligence, a media outlet that specializes in data driven research, predicts that consumer spending will be a significantly smaller portion of the global aerial drone market in the near future. UAV systems used for military purposes will quickly dominate the market and require smaller, niche drone manufacturers to expand their portfolio. The difference in the civilian drone market as compared to the Defense industry is an order of magnitude greater. Autonomous drones manufactured for defense usually have much more complicated functionality and require substantially more development time. The Figure 9 is the amount of money being spent on development of UAVs for military defense purposes will continue to rise in relation to the amount of money being spent on commercial UAVs Business Insider Intelligence [BII] (2016).

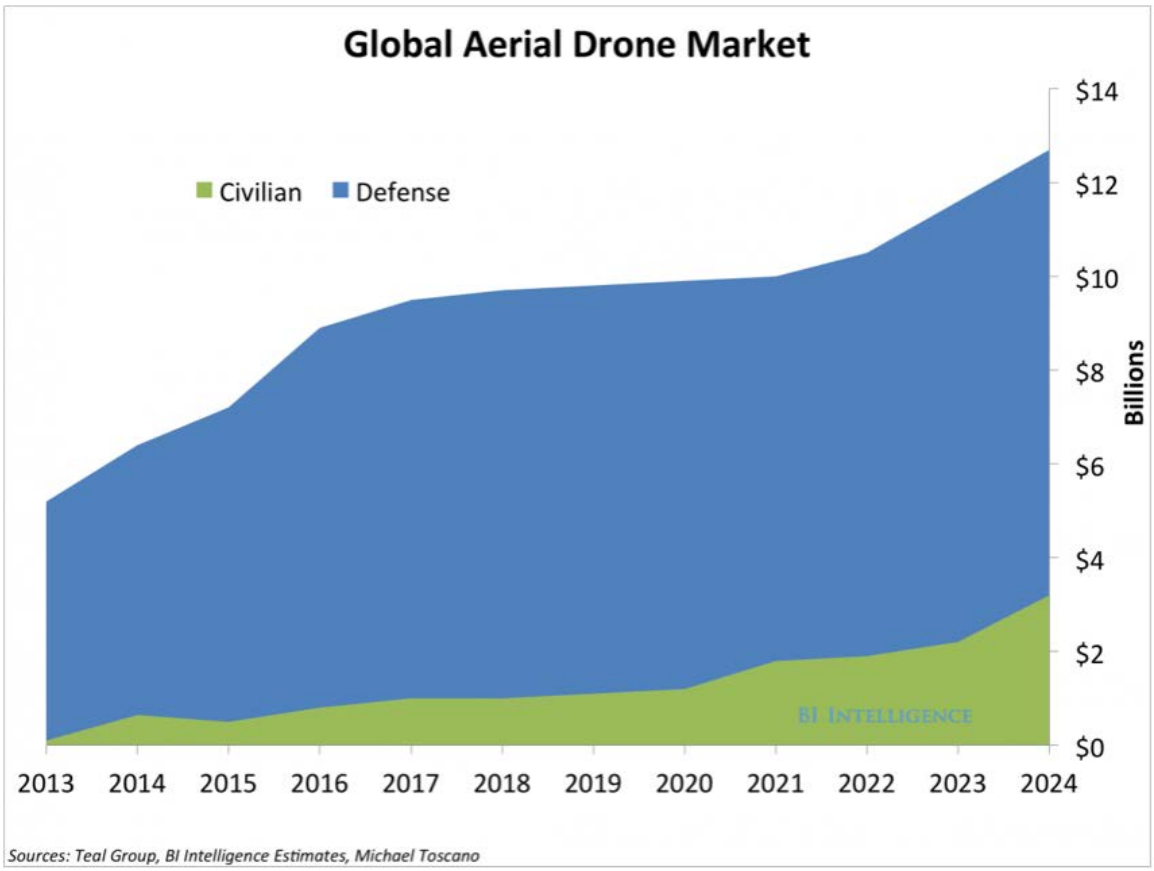

Figure 9. The Drone Report: Market, Forecasts, Regulatory, Barriers, Top Vendors, And Leading Commercial Applications.. Source: Business Insider Intelligence [BII] (2016).

(2) Industry's Autonomous Driving T&E Methodology

Comparatively, the autonomous vehicle industry has the most mature T&E methodology of all the current autonomous systems in use. Autonomous vehicles have been in use since the 2004 DARPA challenge. There are various methodologies currently in use and facilities such as the University of Michigan's Mcity facility that are dedicated to validating vehicles' autonomous software systems. The accelerated rate at which autonomous vehicles are driving on our roads is specifically due to the collaboration of the auto-industry, government, academia and technology companies who have come together in a short period of time to resolve consumer needs.

The most popular T&E method for verifying autonomous systems on vehicles is a form of accelerated testing developed by engineers (Hue Peng, director of Mcity and the

1951 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Roger L. McCarthy Professor of Mechanical Engineering at U-M*)* at the Mcity facility requires autonomous vehicles to be rigorously tested in repeatable components based on extremely difficult real-world driving situations. According to Zhao and Peng (2017) the test method can reduce 300,000 miles of real world driving to only 1,000 miles of test data required to yield equivalent information. In the same report the goal of this test method is to analyze each vehicles' ability to make difficult decision that might result in a fatal accident. Per Zhao and Peng(2017), researchers need to be able to identify the most likely scenarios in which autonomous vehicles will make an incorrect decision and thoroughly vet software until errors can be evaluated and resolved. In the same article, Zhao and Peng (2017) noted that researchers are hoping to provide consumers up to 80 percent confidence that they are 90 percent safer in autonomous vehicles than self-driving ones.

Alongside a focus to reduce the amount of testing for autonomous vehicles, T&E engineers have also developed new methods of validating autonomous vehicle performance. Researcher Ding Zhao has stated that "Test methods for traditionally driven cars are something like having a doctor take a patient's blood pressure or heart rate, while testing for automated vehicles is more like giving someone an IQ test" (Nicole Moore, 2017). Engineers can not only determine the effects of what happens to the passenger and vehicle during an accident but also determine the best way to prevent an accident of occurring.

Verifying and validating how the autonomous systems is triggered and if the software enables the intended preventative action reliably are all part of the evaluation process during development. Autonomous vehicle proving grounds can capture real world data and creating a simulation where variables can be tweaked and changed, reducing the overall amount or real-world test data required to make design decision early on.

More recently, Toyota has adopted a similar test methodology, creating a 60-acre proving ground at Michigan Technical Resource Park in Ottawa Lake to test "Edge Cases" or extreme driving scenarios. Toyota plans to have a facility capable of simulating congested urban environments, slick surfaces and four-lane divided highways with high-speed exit and entrance ramps.

1952 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

(3) Commercial Industry Autonomous T&E Facilities

In 2013, UAV began being regulated by the U.S. Department of Transportation (USDOT) and the Federal Aviation Administration (FAA). Both agencies have partnered with private industry to designate six (6) locations across the United States designated for the T&E of UAS and providing a space where industry and private stakeholder community can conduct advance research and share information. The data being collected will be used to support future FAA policy on critical UAV safety regulations. (Federal Aviation Administration, 2013) The Figure 10 is an image of the six locations across the U.S. designated for T&E of UAS.

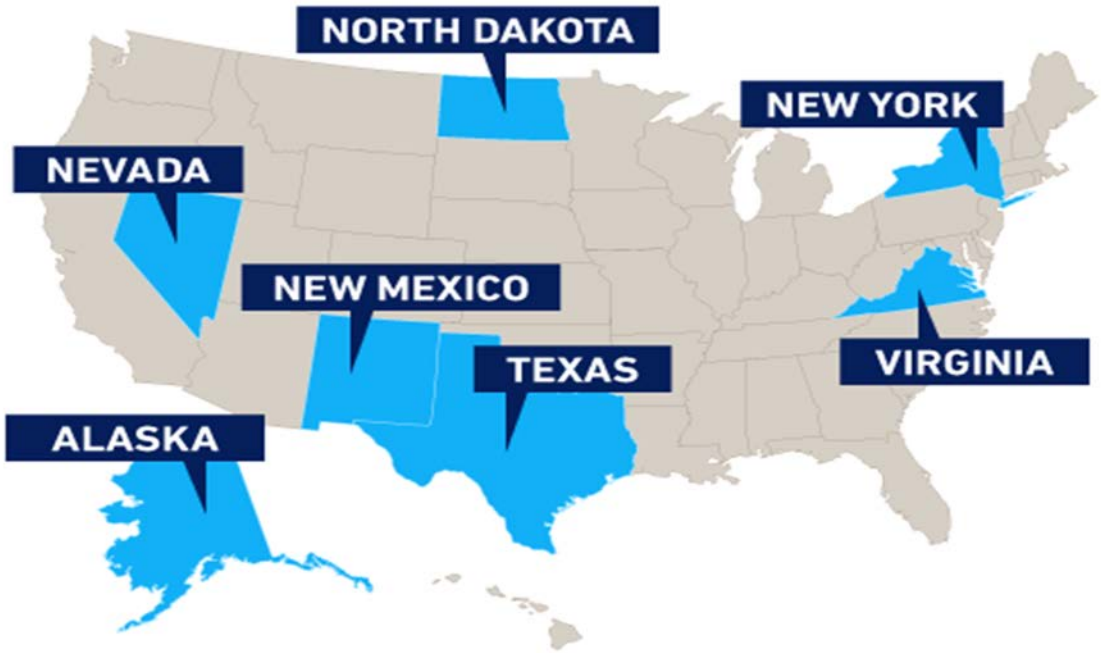

Figure 10. Federal Aviation Administration Report. Source: FAA (2013).

The auto industry has several T&E facilities across the U.S. designated for autonomous vehicles, the primary T&E facility is the Mcity Test Facility, located within the University of Michigan's Norther Campus. Mcity is a 16-acre controlled environment that is capable of simulating both urban and suburban environments prior to deploying

1953 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

experimental vehicles on public roads. Mcity was a joint venture between the Michigan Department of Transportation and the U. M. to create a space where new technologies can be safely tested. Since the development of Mcity, the U.S. Department of Transportation has designated an additional 10 proving grounds dedicated for the test and evaluation of autonomous vehicles. Locations range from the Northern Pittsburg Thomas D Larson transportation center to the southern Texas AV proving grounds and all the way to the Iowa City Area Development Group. The Department of transportation has identified these proving grounds as central hubs for the auto industry and academia to share best practices in the hopes of accelerating autonomous technologies and deploying safer cars on our roads (Mcity Test Facility, 2019). The Figure 11 is an image of Mcity test facility map.

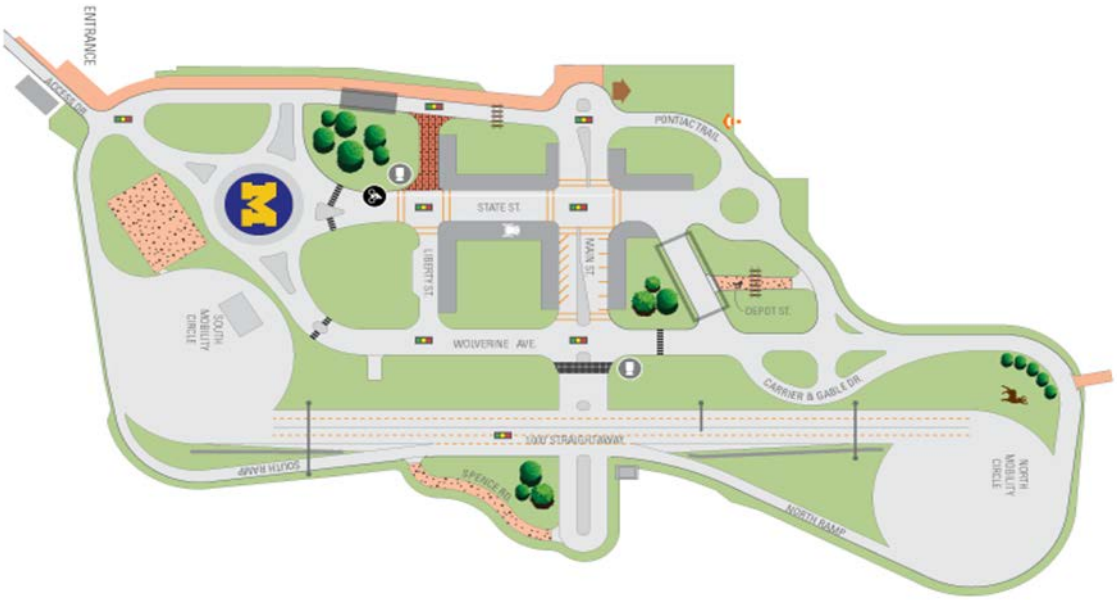

Figure 11. New Software Allows Users to Control Mcity Test Facility.
Source: University of Michigan (2019).

(4) Commercial Industry T&E Software, Simulation and Modeling Strategy for Autonomous Systems

According to Pecheur (2000) the forefront of M&S, the National Aeronautics and Space Administration (NASA) utilizes a suite of autonomous systems to support deep space exploration, from autonomous systems that work independently to keep astronauts

1954 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

on their trajectory towards their destinations, to advanced medical systems that alert ground control when astronauts' bodily vitals drastically change, or system functionality diagnoses a failure. NASA is at the forefront of utilizing autonomous software (Pecheur, 2000).

Based on the amount of unknown external factors and situations NASA systems encounter during space exploration, their systems and software engineers are required to assess a large range of situations when developing autonomous capabilities with limited information accessible. M&S is heavily relied upon as verification of autonomous applications. NASA software engineers utilize model checking, a technique that checks a program for violations or errors in every conceivable way early during the software development process. Software engineers contextualize a sub-system through a mathematic logic and analyze the model's properties during simulated situations to prove its functionality. Once a sub-system has been verified it can then be combined with multiple other structures called Binary Decision Diagrams (BDDs) and represent highly complex models that simulate entire systems. This complex model can then be used in a variety of different simulations and improved incrementally until satisfactory results are obtained.

Once a model has been validated, NASA uses analytical testing to run autonomous applications within unknown environments simulations. These unknown scenarios are simulated environment with ever-changing algorithms used to test the autonomous applications in a broad range of scenarios that have never been witnessed, a systematic exploration to identify errors within the software virtually. Analytical testing can provide a limitless amount of information prior to physical testing early in development of the hardware and at a fraction of the time and cost. Testing is done within the software in virtual simulations, parts, systems and materials can be altered reducing the overall cost of late development changes. NASA believes that analytic testing is the overall best path of increasing reliability of autonomous systems. Through the use virtual testing, NASA test evaluators can virtually simulate failure analysis and corrective action in parallel with development process.

1955 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

E. OPERATIONAL IMPACT OF AUTONOMOUS SYSTEMS

The IOT&E is the final test event for defense acquisitions systems in development and a critical milestone in a program's life cycle. Required by the DOD and by law, it's conducted near a MS C decision to substantiate the operational effectiveness and suitability of a capability in its relative environment and used as the final data point in support of a full rate production decision.

Most technically complex capabilities being fielded by the DOD face a substantial number of hurdles during an IOT&E test. Defense acquisition regulations mandate that soldiers are required to have the proper training prior to test, to operate all systems' subsystems and trouble-shooting procedures prior to the event. Technical manuals are required to be detailed enough to walk soldiers through problems during operations, reliability failures and/or inadvertent user experiences. The IOT&E test is the final exam of the developmental phase of defense acquisition. Autonomous systems must contend with those issues as well as "system" trust and "operational" trust so that operators accept autonomous systems during critical situations. System trust is the operator's trust in the system to independently perform as required and operational trust is the operator's acceptance that the autonomous system is providing a benefit to perform the assigned task over traditional un-autonomous capabilities (Zwillinger, Palmer, & Selwyn, 2014). The U.S. Air Force chief scientist Werner Dahm believes that "Human mistrust of Automation/ Autonomy" is the "major barrier that prevents the USAF from gaining more capability from autonomous systems" (Helle, Strobel, & Schamai, 2016)

In the following chapter, we continue to compare T&E activities for the purpose of identifying specific challenges and future resolutions to DOD's methodology.

1956 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

IV. ANALYSIS OF T&E METHODOLOGIES FOR AUTONOMOUS SYSTEMS

A. DOD'S T&E CHALLENGES OF AUTONOMOUS SYSTEMS AS COMPARED TO INDUSTRY BEST PRACTICES

The purpose of this JAP is to examine the current test methodologies of government programs with autonomous functionality as compared to the T&E methodologies of the private sector in order to identify successful practices that can be used as actionable changes to enhance the qualification and fielding of future DOD autonomous capabilities. This JAP utilizes the test and evaluation methodologies of four programs of records (SREHD, Gray Eagle, Project Perdix and the AMAS system) alongside similar industry systems within the automobile, agriculture, space and drone industry as a basis for comparison. The analysis section of this JAP outlines four significant weaknesses within the DOD autonomous systems T&E methodology as compared to current industry best practices. The data supporting these 4 (four) deficiencies is based upon research identified in the previous section comparing industry best practices alongside the T&E methodology of DOD programs of record.

Below we explore the following DOD T&E weaknesses

- DOD's fragmented T&E process diminishes chances of fielding autonomous capabilities
- DOD's lack of test facilities that can accommodate an autonomous capability concurrently alongside the development process
- DOD's minimal use of M&S during T&E of new systems
- DOD's inefficient Operational Testing of autonomous systems methodology

Major defense acquisition programs follow a standard development cycle; once a requirement has been established and approved by the user, those requirements are then taken by the program office and developed into a request for proposal to industry partners

1957 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

and awarded to the overall best proposal that meets the government's selection criteria. A contract is established, and contractors begin developing the system in conjunction with government oversight to ensure cost, schedule and performance metrics established within the contract are being met. Systems and subsystems are then tested and evaluated by the government T&E team to ensure performance requirements are being satisfied prior to full-rate production and fielding. The T&E process continues until the government is satisfied with the system's level of performance and/or the user accepts limitations against requirements. Operational Test and Evaluation (OT&E) activities, typically take place near the end of the engineering maturation phase and are both schedule and cost drivers. Technical issues identified during OT&E can be catastrophic during development, especially for autonomous functionality that is linked to human safety.

As in the case of SREHD's operational test event, in which operators were evaluated on how successful they could utilize all SREHD's capabilities to navigate lanes with hidden explosive devices. This test was conducted at the end of the DT&E phase due to the need to utilizing mature systems and software together. Thousands of hours were spent on hardware and software changes to ensure the system could meet the user requirements, but very little time was spent with the system in actual soldiers' hands. Per (James & Chang, 2017) the test was ultimately a failure because the consensus from the user representatives was that the system found to be non-operationally effective in comparison to the already fielded hand-held systems which were quicker and more, more versatile an in conjunction with the operator's awareness, more efficient at identifying threats.

In contrast, the autonomous systems industry has overcome these issues by establishing a continuous process of experimentation, testing and evaluation. Since there are no gaps in the development team structure, "real-world" data is continuously utilized to identify system problems and assist with better decision making. Statistics and human factor analysis are used throughout the system's life cycle to recognize system limitations early on and assist program managers with adjusting resources to better fit the needs of its customers. Commercial companies like autonomous electric vehicle manufacturer, Tesla and drone manufacturer DJI, both utilize a process of continuous real-world data collection

1958 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

throughout the entire life cycle of their autonomous systems. The continuous data collection enables quicker iterations of products to market and retroactively provide them with upgrades that increase the performance of their autonomous functionality. Continuous experimentation and data collection throughout development reduces the risk of operational test failures.

B. AVAILABILITY OF TEST RESOURCES THAT CAN ACCOMMODATE AUTONOMOUS SYSTEMS

In the DOD *Autonomy Report*, (2012) the Secretary of Defense, stated that "DOD's testing infrastructure will not be able to support future testing of new technologies such as hypersonic and autonomous systems without increased funding." This was also acknowledged by the DOT&E who rebutted major sections of DBB's report but affirmed that the current infrastructure of the DOT&E was not fully postured for the future and requested a follow-on study to assess the state-of-the-art technology to close the capability gap. Additionally, infrastructure was also reported to be an issue by the STAT T&E Center of Excellence which stated, "Many of the necessary processes, systems, test infrastructure and other capabilities simply do not exist, and may not have even been conceived at this point" (Parson & Ahner, 2016). The DOD needs to invest in test facilities and test evaluators that can accommodate an autonomous system in order to be successful in the future.

Based on the data collected for this JAP, all four case studies used to examine DOD's T&E methodology for autonomous systems utilized traditional man-in-the-loop type facilities and equipment as a means of qualification. In none of the four case studies were test facilities and/or equipment developed alongside the development of the autonomous capability to ensure that a better more efficient method of testing was available. Logically, autonomous systems are still an insignificant percentage of capability within the military and, with limited budgets, DOD has not prioritized funds for specialized facilities and equipment to test autonomous systems. However, until program managers, alongside the test and evaluation community, identify gaps in the T&E methodology of AS, programs will continue to be hampered by inefficient, expensive and unadaptable T&E methodology.

1959 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

As an example, the SREHD T&E methodology required pre-existing lanes created for testing hand-held detectors. The AMAS's test facility is the Army's primary test venue for qualifying medium/heavy military vehicles; Gray Eagle is tested in airspace used to qualify the military's fleet of fighter jets; and Project Perdix is tested over China Lake, a naval weapon test site. Based on our research, currently none of these facilities use adaptive instrumentation needed to evaluate the system's ability to learn and adapt to its environment. Inadequate instrumentation becomes a critical issue when trying to identify the root cause of a failure and leaves test operators and data collectors vulnerable to "false positives" or test failures that are due to systems trying to adapt to environmental changes.

Alternatively, industries like the autonomous driving industry work together to advance test facilities for autonomous vehicles with the vision of modernizing vehicle proving ground facilities for the future. The University of Michigan and industry partners have invested $20 million in the Mcity test facility specifically to evaluate autonomous vehicles through a broad range of urban and suburban environments.

The Mcity proving ground can simulate several types of road surface conditions and structures while remotely monitoring a vehicle and passenger conditions. Mcity is also one of the only vehicles proving ground facilities to provide infrastructure capable of dedicated short-range communication, which is the future of autonomous vehicle communication enabling advanced coordination and cooperation that will reduce congestion and improve traffic flow in the future. The test facilities provide the autonomous vehicle industry a test bed to compare its simulated "virtual" performance with actual roadside data that can be evaluated in real time to help engineers identify changes and deficiencies quickly and turn around corrective alternatives.

Theoretically, if the AMAS IPT could duplicate the type of test facility that industry is using to qualify autonomous vehicles, DOD would have the capability of replicating multiple terrain types, environments, and threats at a single test facility versus having to fund and transport equipment, test hardware, and people to multiple test sites. The time and cost involved with transporting and maintaining multiple types of military vehicles to test and evaluate the AMAS system could be used more efficiently to expedite development of the overall test program.

1960 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Another significant limitation facing DOD's T&E community is the lack of expertise working with autonomous systems. A report issued by the Scientific Test & Analysis Techniques Center of Excellence, "Test and Evaluation of Autonomous Systems," identified that DOD's current T&E workforce lack personnel who can apply new methodologies for the future autonomous system testing.

Leading autonomous systems technology firms imbed their T&E teams within their design teams to shrink development times and increase system reliability. Companies such as Autonomous Solutions Inc. (ASI), the current market leader in autonomous farming technology, utilize a single facility to both design and validate their autonomous systems. Test engineers work in tandem with the designers, programmers, and mechanical engineers to expedite the validation process of subsystems in simulated "operational environments" to verify functionality early in the development process. (Nielsen, 2016) The synergy created by having onsite test facilities available early in the development process assists with the system education process and allows evaluators to understand the full range of capabilities of autonomous systems.

Based on the four provided examples, the T&E methodologies for the government autonomous programs are typically repurposed man-in-the-loop test methods and facilities that are utilized to verify and validate functionality. Most of these tests take place on MRTFB with personnel who do not specialize with autonomous technology and were not part of the technology demonstration phase of the program. In addition, these tests are typically large and exhaustive efforts to ensure the maximum amount of conditions are evaluated for stakeholders to determine a capabilities readiness.

Conversely, industry has identified the profit to be made by the growing "smart" commercial sector and have heavily invested in specialized personnel and facilities to rapidly provide autonomous products into the marketplace. Newer products are based off designs of older products and do not require an extensive amount of testing, only incremental validation of new functionality. Overall, industry embraces partnerships with agencies who specialize in the T&E of autonomous capabilities, which can rapidly iterate on test results and provide the latest technology to assist with the verification and

1961 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

validation. The differences between the two methodologies drastically impairs the DOD's ability to design, test and field autonomous capabilities.

The DOD, as a non-profit agent, must provide test resources for several thousand programs of record across the country, whereas emergent startup companies can profit off the autonomous systems boom and create niche T&E facilities. Autonomous programs of record are still in the infancy phase and DOD does not have the resources to convert the current T&E facilities to specialized autonomous systems test facilities. Program offices developing new autonomous systems, in conjunction with their prime contractors, will leverage private test facilities and personnel to level the playing field. PMO's will utilize the changes made to Army Regulation 73-1 (AR 73-1), which requires ATEC to minimize redundant testing and utilize both contractor data and test facilities to accelerate development and get capability into the warfighter's hands. In the future, as the need for more autonomous capabilities grow, the DOD will have to assess if there is still a need for government owned, government operated test facilities specifically for autonomous systems.

1. DOD's Minimal Utilization of M&S during T&E of New Systems

Based on the research for the four programs within this JAP, M&S data was only utilized as a tool to prototype and analyze maturing technology. This JAP was unable to identify any M&S being used as a T&E methodology alternative to real-world, physical hardware testing. In most test cases we identified within this JAP, the four systems used M&S to corroborate existing data and verify performance metrics prior to physically testing hardware. A primary reason the DOD doesn't use M&S more liberally throughout system development is because the T&E community lacks a robust M&S test capability that can stress validated models within an integrated virtual environment (J. Brabbs, S. Lohrer, P. Kwashnak, P. Bounker, M. Brudnak, 2019).

During the development of the AMAS system, M&S was utilized to simulate the AMAS architecture within a virtual testbed. Engineers were able to evaluate what the AMAS system was capable of prior to physically running the system on a vehicle. Unfortunately, because of how the AMAS system uses several sensors to capture and relay

1962 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

information to the vehicle, the T&E community was unable to use the information to pre-plan test scenarios or capture any valid performance metrics. Vehicles were still required to be equipped with the AMAS system for testers to complete their analysis of the capability (D. Pirozzo, J.P. Hecker, A. Dickinson, T. Schulteis, J. Ratowski, and B. Theisen, 2019).

Gray Eagle was similarly developed with the same methodology. Government test and evaluators only utilized a virtual model of the Gray Eagle after the capability was complete and real-world data could be acquired to verify performance. Currently, the only government utilization of virtual simulation is to train Gray Eagle operators, but virtual testing could have been utilized to mitigate reliability issues that plagued the system early in development.

Project Perdix hasn't undergone formal developmental testing but there is no indication that DOD test and evaluators are utilizing virtual simulation software to evaluate performance. Only test data that was obtainable was taken from real world testing, evaluated for the purpose of increasing the size of the drone swarm, and evaluating new test environments. Simulation and modeling could be utilized during initial test events to mitigate user interface issues and determine ideal conditions for future test events.

Finally, during the development of the SREHD capability, the government did not utilize SREHD M&S data to validate changes made to the system. Every single design change required additional tests that resulted in additional time and cost against the acquisition program baseline. The government IPT did not request SREHD software models be kept up to date with changes made later in development and was unable to utilize virtual simulation to validate/verify critical reliability engineering change proposals (ECPs) efficiently. The only means of verification was to physically test and evaluate system performance by running the system over test lanes at Yuma Proving Grounds and AP Hill test facilities. If the government development team had contractually obligated the SREHD contractor to maintain virtual models of the SREHD system, months of test and evaluation could have been reduced without requiring a 12-month period of performance (PoP) extension and a substantial cost overrun.

1963 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Alternatively, the federally funded National Aeronautics and Space Administration, (NASA) does utilize simulation and modeling at the beginning of the development process to test and validate concepts prior to design completion. Once models have been validated, NASA engineers can run virtual software simulations of entire complex systems within new environments to identify errors and increase reliability. Additionally, since testing takes place within a virtual environment, parts, materials and subsystems can be altered quickly, reducing the overall cost of late development changes.

Programs like SREHD, utilized M&S early in development, as a means for engineering teams to plan budgets, resources and judge the complexity of technical requirements. Once initial prototypes were completed, resources were focused on getting hardware and software mature enough to meet requirements but without regard of maintaining those changes to the virtual simulation. Developing complex software structures such as NASA's binary decision diagrams (BDDs) to simulate autonomous functionality before and throughout the development of autonomous systems, is a proven method of reducing both the cost and time required to physically validate autonomous functionality in complex systems.

2. DOD's Inefficient Operational Testing Of Autonomous System Methodology

Based on the information being presented, it is more likely that industry will be more capable of reducing the amount of resources required during T&E to bring autonomous systems to the market. The primary reason for our hypothesis is that the commercial sector for autonomous products is smaller, more niche and capable of focusing on data derived from experimentation during development testing which can be used to seize the scale of relations and reduce the need for redundant and inefficient testing. This enables industry to focus future tests on only the most critical components of an autonomous capability. The autonomous automotive industry already utilizes test facilities that incorporate the "Hue Peng" methodology of testing the I.Q. of autonomous vehicles rather than its ability to make identical decisions given different types of situations. This methodology not only increases the level of awareness of the autonomous capability but also reduces the amount of testing required to validate complex systems (Peng & Zhao,

1964 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

2017). The Hue Peng methodology is in direct conflict with DOD's T&E methodology that requires testers to verify and validate all system parameters. This methodology adapted to the Gray Eagle's autonomous liftoff and landing capability could have reduced the time needed to qualify this unmanned system.

The DOD uses information gained during the OT&E period to assess a system's operational effectiveness and operational suitability during a realistic simulated combat scenario. The *Role of Autonomy in DOD Systems* by the Defense Science Board (2012 summed up the issue of testing autonomous systems best in their report, "Testing all System of System requirements of all the systems is impossible." With the inception of autonomous systems on the battlefield, DOD needs to dynamically change its T&E methodology for operational testing to a more efficient and effective means of verifying and validating operational requirements that will assist in accelerate development and fielding.

Operational test events planned for the end of the EMD phase need to evolve into operational experimentation initiated in the technical demonstration phase The DOD has acknowledged the issues of the standard FAR based acquisition process and provided new guidance called, middle tier acquisition (MTA) authority issued by Congress in the FY16 National Defense Authorized Act (NDAA) Section 804. The authorization establishes an interim adaptive acquisition process that enables the PMO the opportunity to accelerate capability development and field prototype hardware within 5 years. MTA provides the PMO the authority to experiment with mature technologies in an operational environment from the beginning of the acquisition and enter into production within 6 months (Office of the (Under Secretary of Defense for Acquisition and Sustainment [USDAS], 2020).

Each PMO needs utilize tools and authorities like MTA to incorporate an operational experimentation strategy that gets autonomous systems in the hand of the actual warfighter as soon as feasibly possible. The benefits of early feedback by an actual user representative in a relevant environment will assist in both, shaping future test events while accelerating development. Typically, autonomy is incorporated into military systems to provide functionality that reduces burdens for safety critical tasks, such as maintaining head height of a sensor on a mine detection system or constantly monitoring

1965 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

communication systems for the purpose of safely navigating the skies. The T&E of autonomous systems require the evaluation of these system's behavior in both defined and undefined environments. System autonomy is derived from machine learning algorithms which inherently behave in varies ways to the same inputs overtime, since their knowledge increases over multiple operations over time. Fundamentally this means "that one successful test does not guarantee that the system will pass the same test on the next run" (Art & Philip & Helle, 2016). Non-deterministic behavior is a key challenge facing the DOD T&E community, requiring investment into advanced test simulation techniques, that significantly reduce the amount of test scenarios needed, in favor of fewer, more effective test. In the case of SREHD, early experimentation would have assisted the PMO in directing more development with the user interface and mitigated negative user feedback late in the development cycle.

The DOD's issues with aging test facilities, constrained resources for T&E and strict adherence to processes designed around testing "manned" systems is a self-imposed problem and unique to DOD's acquisition process. The commercial sector for autonomous systems created new and adaptive T&E methodologies specific to the needs of its products. As in the case for the automotive industry utilizing the "Hue Peng" methodology, which reduces the time spent, testing vehicles on the road to specifically what is required to verify the autonomous systems decision-making process.

Alternatively, the autonomous systems farming industry partners with their customer base specifically to obtain better T&E data during the development process. The DOD equivalent to this example would be for a system like the AMAS capability to be operationally tested during development by a deployed military transportation division. Unfortunately, the program stagnated and never progressed past the technology demonstration phase and has since transitioned into the Expedient Leader Follower (ExLF) program (DEFPOST 2018). Real-world developmental testing alongside laboratory test and evaluation is a critical step in advancing the T&E methodology for autonomous programs or record.

1966 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

V. CONCLUSIONS

A. ADAPTING INDUSTRY'S T&E METHODOLOGY

The purpose of this JAP was to collect information on DOD's current T&E methodology of autonomous systems through the analysis of case studies on four current programs of record (Gray Eagle, SREHD, and AMAS & Project Perdix) and identify corresponding industry T&E trends that could be used to successfully enhance DOD's T&E methodology for the future. Drawing comparisons between the defense acquisition process and private industry development process can be dangerous. The DOD is a non-profit organization that is responsible for ensuring the protection of U.S. citizens and national interests around the world and by proxy, that its military is outfitted with the most effective weaponry.

Private industry on the other hand is more concerned with developing products around commercial interests, maximizing profit and ensuring products meet the minimum safety standard required by government regulation. Pass/fail decisions are less relevant for commercial viability. This JAP acknowledges that not all best practices and commercial trends can be transitioned from industry to DOD's T&E methodology but based off of the analysis of the four systems within the JAP, we can conclude that the current DOD T&E model has significant weaknesses and recommend several industry T&E best practices that could be adopted by the DOD T&E community to advance methodology for military autonomous systems development.

B. ADVANCING DOD'S T&E METHODOLOGY FOR AUTONOMOUS SYSTEMS

As we framed our ideas for the JAP, we started out by seeking answers to two specific questions.

(1) Primary:

- What unique challenges are presented by autonomous systems to the Department of Defense's test and evaluation communities?

1967 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Based on the research covered within this JAP, the DOD T&E community face several unique challenges that industry does not have to overcome. The challenges the DOD face in the T&E process for autonomous systems is like the development of other highly complex government acquisition PORs. The critical obstacle is to determine how the T&E community assesses the non-deterministic behavior of autonomous systems. We determined that answer to this question is exacerbated by the four specific challenge areas within the DOD T&E acquisition process for AS.

- DOD's fragmented T&E process that diminishes chances of fielding autonomous capabilities
- DOD's lack of test facilities that can accommodate an autonomous capability concurrently alongside the development process
- DOD's minimal use of M&S during T&E of new systems
- DOD's inefficient Operational Testing of autonomous systems methodology

This JAP concludes that the hurdles facing the DOD T&E community are due to current infrastructure, equipment and technical personnel that were created around the T&E of man-in-the-loop type systems. The military's autonomous capabilities of tomorrow require facilities that are capable of testing autonomous subsystems and systems in sync with development, as well as the trained personnel required to evaluate AI and machine learning over the life cycle of the system. The DOD T&E community need access to developmental data earlier in the life cycle of major development programs in order to efficiently evaluate the growth and maturity of autonomous systems. Additionally, DOD's T&E methodology has not sufficiently embraced M&S from the beginning of the life cycle, prohibiting virtually simulated testing of autonomous functionality early on, that would reduce the amount of time and resources needed to qualify systems. Finally, the DOD T&E methodology for operational testing requires a paradigm shift to be more effective and efficient at evaluating autonomous systems in relevant, realistic environments. Industry already embraces early real-world testing of autonomous systems for the purpose of

1968 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

evaluating the suitability and effectiveness of potential designs. The DOD should initiate methods of parallel verification and validation of operational experimentation, that would enable expeditionary forces to evaluate the effectiveness and suitability of autonomous systems prior to and throughout the EMD phase.

(2) • Secondary:

- Does DOD have the correct resources to conduct tests and evaluations of autonomous systems?

The DOD T&E community face unique challenges based on regulatory and statutory guidelines in the Federal Acquisition Regulation process, which prohibit adaptive and reflexive strategies required to keep pace with the constantly changing technologies of tomorrow. The DOD is also constrained by not having specialized personnel and processes in place that maximize the unique capabilities of autonomy. Examples like Mcity in Michigan developing specific test facilities and technologies to evaluate vehicles with autonomous capabilities or agencies like the FAA and USDOT developing policy's for the advancement of T&E research are evidence that the T&E community supporting the autonomous systems industry has rapidly developed new and better technologies. Even though most POR are developed in conjunction with defense contractors, most of the verification and validation of requirements still take place at DOD run facilities, limiting access to the latest innovative T&E methods and techniques. Some of these issues can be addressed, through the use of the adaptive acquisition framework, providing PMO's the authority to determine and tailor the most efficient method of acquiring, maturing and fielding a capability, delivering a better solution faster to the warfighter (USDAS 2020). Through the use of MTA, the PMO has the ability to leverage new technologies, contractor test data and government experimentation data for the purpose of maturing and fielding a capability that would otherwise take several years based on the typical major capability acquisition pathway.

C. FINAL THOUGHTS

Through the exploration of the DOD T&E methodology for autonomous systems, this JAP was able to identify several keyways in which DOD can advance its T&E process to be more in line with industry trends.

- DOD autonomous systems PORs should consider the addition of clauses in contracts that require contractors to create, maintain and utilize virtual models for the specific purpose of efficiently simulating test of autonomous functionality. These clauses can be used to increase the level

1970 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

of confidence of virtual models that can expedite development test and evaluation.

- DOD needs to increase funding and education in support of advancing the autonomous test capabilities at APG and YPG and test facilities. The education of the T&E community and restoration of DOD test facilities are critical to providing the warfighter the cutting edge in capability. To include MRTFBs retaining the capability to replicate multiple terrain types, environments, and threats at a single test facility versus having to fund and transport equipment, test hardware, and people to multiple test sites.

- DOD should consider incentiving PORs to develop T&E strategies that include parallel verification and validation of operational effectiveness and suitability during the EMD phase. Continuous operational evaluation of autonomous subsystems would provide contractors valuable data on the effects of machine learning outside of the laboratory environment, provide decision makers valuable information on how better to manage funding needed for corrective action strategies, and give users information on how to tailor requirements to only what is critical for operational effectiveness. With the use of expeditionary forces providing globally deployed soldiers' innovative solutions to address urgent needs operational, T&E development process should be included to provide as much information as soon as possible on operational effectiveness and suitability**.**

- DOD must establish a more consistent process for experimentation, T&E and updating already fielded autonomous capabilities. To note, defense programs like Gray Eagle, have a process in place to incrementally add enhancements but the ability to improve upon autonomy post initial fielding is only reserved for the larger MDAP initiatives. Advances in technology have enabled the tech industry to sell products in the marketplace with a limited feature set initially and continue to increase

1971 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

> that products' capabilities over time. If DOD were to adopt a similar methodology of fielding autonomous systems with limited capability and over time increasing functionality to bring enhanced autonomy retroactively, then DOD autonomous systems would require less test and evaluation, at a reduced cost and less schedule delays.

Ironically, it is now industry leading the way in the technology fields of artificial intelligence, machine learning, and virtual simulated testing that originally were government defense research initiatives. Fortunately, during the time it took to evolve our JAP, the DOD has initiated policies and postures that are intended to totally change the dynamic of how the military brings advancements and capability to the field. Army Future Command is the Army's primary command stood up in 2019, for the purpose of soliciting industry's best and brightest to rapidly evolve technology and demonstrate capability quickly for the warfighter. The Army has recognized that only through embracing rapid innovation of industry will we be able to keep ahead of our near-pear threats. It is our hope that the DOD will keep pushing ahead and use the information contained within this JAP to continue creating new policies and regulations that will facilitate the T&E of autonomous systems within DOD systems.

13. SUPPLEMENTARY NOTES

14. ABSTRACT

With the ever-increasing complexity of military operations and adversary abilities, merely possessing advanced autonomous capabilities is not sufficient for battlespace superiority. Human-Autonomy Interfaces (HAIs) must be designed to ensure effective collaboration and coordination between human operators and the autonomous systems available to them. This report details the methods and results of a Cognitive Work Analysis (CWA) that informed the development of an integrated suite of autonomous tools that enables an Air Mission Commander (AMC), teaming with autonomous capabilities, for example, play calling, route planning, and asset allocation, to effectively command and control a team of multiple unmanned and manned aerial systems to complete an air assault mission. This report will highlight the practical applications that the CWA results provided for generating designs for the HAIs. In addition, feedback from Army Aviation Subject Matter Experts (SMEs) during the simulation interview is discussed since these results not only informed system development and design but illuminated critical details to ensure that the most ecologically valid and operationally relevant tasks and events were selected for the program's empirical evaluations.

EXECUTIVE SUMMARY

Advanced autonomous systems are being developed to enable a single operator to have the ability to effectively and simultaneously manage, command, and control a team of multiple Manned-Unmanned (MUM) vehicles. Critical to the teaming of human operators with autonomous systems is the Human-Autonomy Interface (HAI), which should be designed to ensure effective collaboration and coordination between the human operator and the autonomous systems available to them.

The first step in our HAI design process was to gain a deeper understanding of the complex work that an Air Mission Commander (AMC) performs during air assault operations. A Cognitive Work Analysis (CWA) was therefore conducted to uncover the behavior-shaping constraints of an AMC, including a set of semi-structured interviews with Army Aviation Subject Matter Experts (SMEs). Results of the CWA will be discussed, as well as examples of how the results informed the design of the HAI, the variables and constraints the suite of autonomous systems reasoned about, and the selection of events, tasks, and details later used for empirical evaluations of the human-autonomy team during simulated air assault mission.

1985 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

I. INTRODUCTION

New and recently developed autonomous systems, decision-aiding technologies, and Human-Autonomy Interfaces (HAIs) have the potential to assist an Air Mission Commander (AMC) tasked with conducting Manned-Unmanned Teaming (MUM-T) operations from the cockpit of a Vertical Takeoff and Landing (VTOL) aircraft. However, many of these technologies have failed to appreciate the critical role that human-to-autonomy communication and coordination play in successful human-autonomy teaming, instead they focus on optimizing separate human and autonomous components and leaving the design of interfaces and team processes as an afterthought [1]. However, team performance is more than the sum of the abilities of the individuals that compose the team [2, 3], and simply pairing the best human with the best autonomous system will not necessarily result in the best performance.

Effective collaboration is essential to the success of human-autonomy teams, especially in the context of sociotechnical systems where multiple agents, both human and autonomous, must work together to solve complex problems [1]. Reference 4 identified three stages for enabling successful collaboration:

- Understand—develop an accurate representation of the domain and ensure that the autonomous system can reason about relevant domain aspects
- Generate—design interfaces that enable a rich coupling between the human operator and the autonomous systems
- Validate—evaluate the human-autonomy team in a realistic test environment

This report details the methods and results of the initial Cognitive Work Analysis (CWA) designed to inform each stage for the development of Tasking and Execution of Collaborative Unmanned and Manned Systems with Autonomy (TECUMSA), a system designed to achieve the goals of the Synergistic Unmanned Manned Intelligent Teaming (SUMIT) program. Also covered in this report are examples to highlight the practical application of the CWA results, including designs that were generated for TECUMSA's HAI as well as critical aspects of an air assault mission that were integrated into the logic of the autonomous systems, for example, air route optimization parameters. Finally, this research will detail the results of the collaboration with Army Aviation Subject Matter Experts (SMEs) to ensure that the most ecologically valid and operationally relevant tasks and events were selected for the SUMIT program evaluation of the human-autonomy team.

II. UNDERSTANDING ARMY AIR ASSAULTS

In an air assault, mission helicopters transport ground-based military forces and supplies in order to gain a military advantage. Mission objectives include penetration and security of strategic terrain and engagement and neutralization of enemy forces. During an air assault mission, the AMC is the overall mission leader with delegated authority over decision making and providing oversight and directives to up to 16 or more aircraft in a hostile, dynamic, and largely unpredictable environment. While adding Unmanned Aerial Vehicles (UAVs) to the AMC's resources has the potential to benefit mission performance, it could also increase the AMC's already high workload. Thus, autonomous technologies that assist the AMC in

1986 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

managing UAVs, such as Cooperative Control Algorithms (CCAs) that plan optimal routes, Intelligent Agents (IAs) that recommend optimal courses of action, and autonomic frameworks that monitor ongoing events, are critical for MUM-T missions.

IAs are being developed that can recommend a plan to satisfy an operator request, for example, provide overhead surveillance, while taking into account relevant situational variables, such as fuel use and time enroute [5]. Reference 6 illustrated how these IAs reason, as shown in Figure 1, using a scenario in which an operator manages three UAVs (FN-11, FN-12, and FN-13) and two Unmanned Ground Vehicles (UGVs) (TR-21 and TR-22). In this example, all of the unmanned vehicles are equipped with Electro-Optical (EO) sensors, two unmanned vehicles (FN-12 and TR-21) also have an Infrared (IR) sensor, and the UGVs have better sensor resolution than the UAVs. The operator's task in Figure 1 is to image Point Charlie on a cloudy day, thus making IR sensors more capable than EO sensors. In this scenario, the IA reasons about the time it takes each unmanned vehicle to get to Point Charlie as well as their respective capabilities.

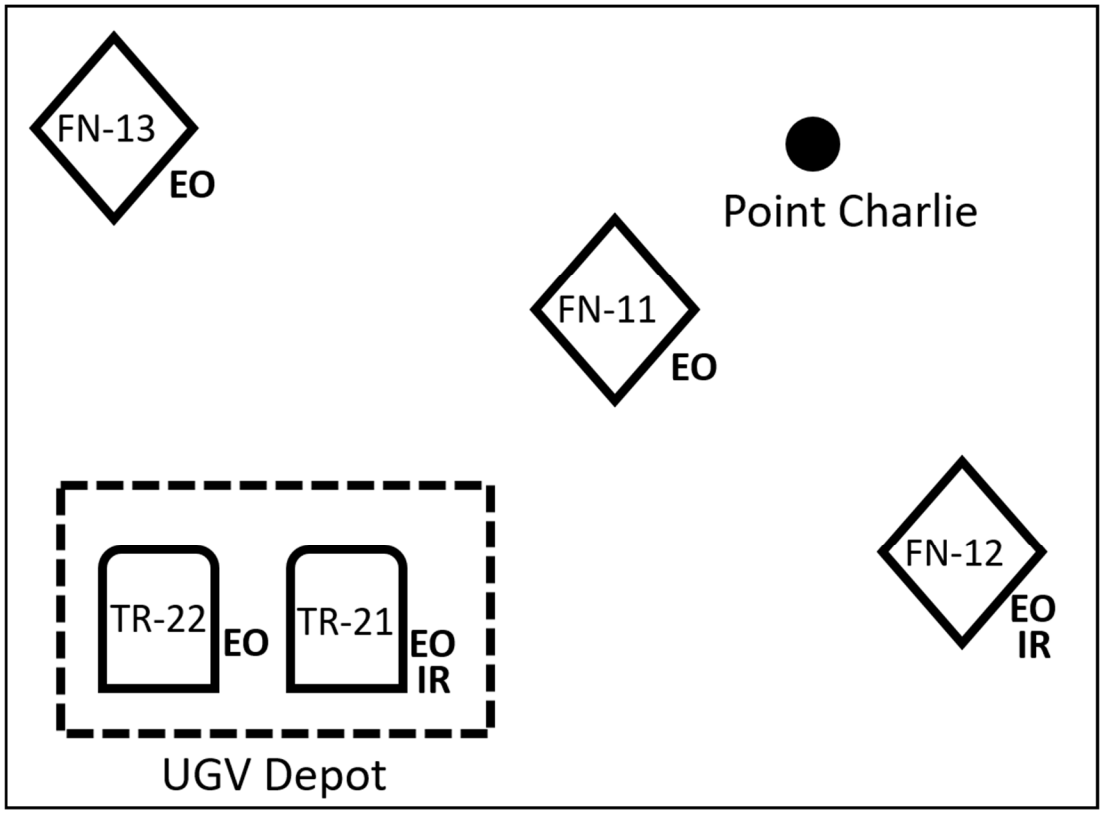

Figure 1. IA Reasoning Example Scenario [6]

The IA's reasoning is based on Pareto efficiency, whereby a plan is eliminated if another plan is better on all relevant dimensions [6]. Figure 2 illustrates the Pareto efficiency of each unmanned vehicle for this task, with Pareto optimal vehicle choices (FN-11, FN-12, and TR-21) on the dashed line. For example, FN-11 can get to Point Charlie the quickest so it is a better choice than FN-13, which has the same sensor capabilities but is farther away. Similarly, TR-21 is more optimal than TR-22 because even though both unmanned vehicles can reach Point

1987 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Charlie in the same amount of time, TR-21 has better sensor capabilities, that is, an IR sensor. This leaves three Pareto optimal vehicles for the operator to choose from:

- FN-11—fastest speed and worst capability
- TR-21—slowest speed and best capability
- FN-12—average speed and average capability

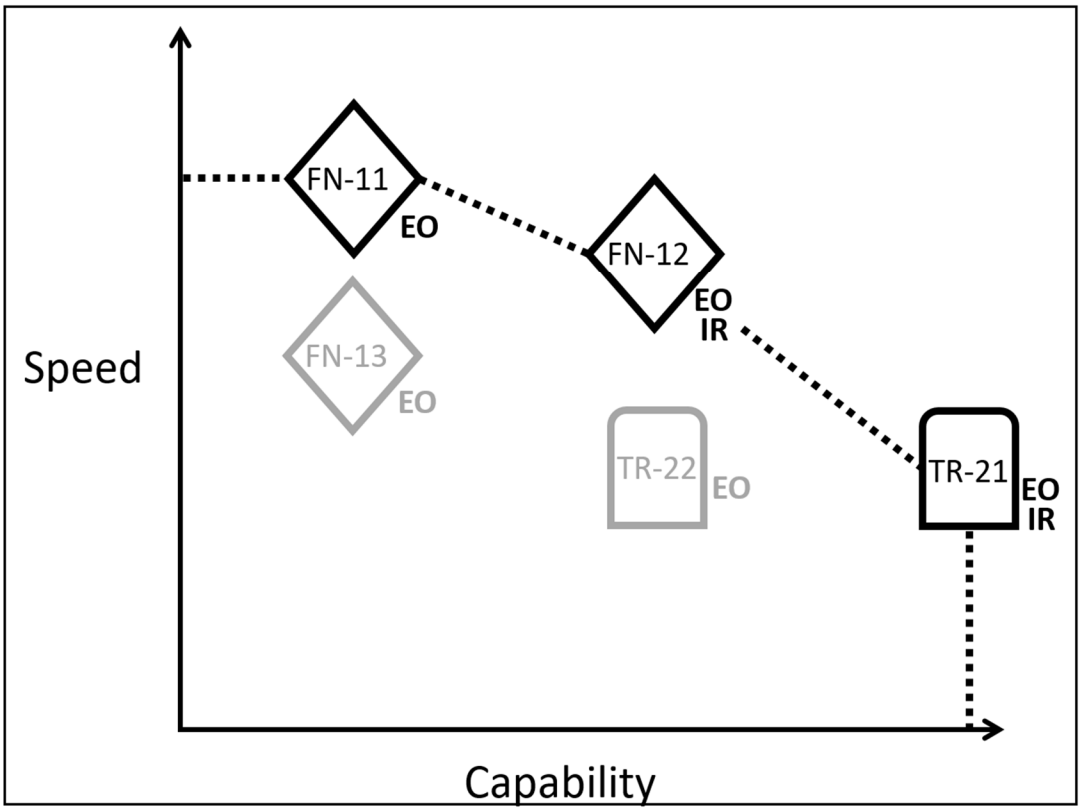

Figure 2. Pareto Optimal Vehicles Located on Dashed Line With Grayed Out, Sub-Pareto Optimal Vehicles [6]

The key to this process lies in the IA's Cognitive Domain Ontology (CDO), which is a representation of domain knowledge used to categorize situations, develop hypothesis, and plan and recommend courses of action [7]. With a CDO that accurately represents the constraints of the mission, which is in this case speed and sensor capability, the IA can rank and compare plans to determine which unmanned vehicle is the best to use. Thus, research to develop an IA that can support an AMC during an air assault mission must begin with an understanding of the work domain.

Researchers and developers can gain this understanding using a CWA, which is a set of methods used to understand how situational dynamics impact performance [8, 9]. For this effort, data were sourced from Army doctrine on procedures, tactics, and regulations, along with extensive interviews using several different methods, as described in Section V.A, with experienced AMCs.

1988 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

III. GENERATING USER INTERFACES

Although understanding the mission domain is necessary for autonomous systems to improve mission performance, it is not sufficient. Interfaces are needed that not only reflect the constraints and relationships of the complex work environment but also enable a rich coupling between the human operator and the autonomous technologies in order to bridge [10] gulf of evaluation and gulf of execution. The size of the gulf of evaluation depends on how well the human-autonomy team can observe, perceive, and understand the state of the world in terms of their intentions, for example, to see the best move on the chess board, while the size of the gulf of execution depends on the effectiveness of the actions or controllability the human-autonomy team has to achieve its goals [6]. However, if there is a poor coupling between the humans and autonomous technologies, for example, incompatible intentions, insufficient understanding of competency boundaries, then another gulf, known as coordination gulf, is introduced that creates additional uncertainties for each component, as shown in Figure 3.

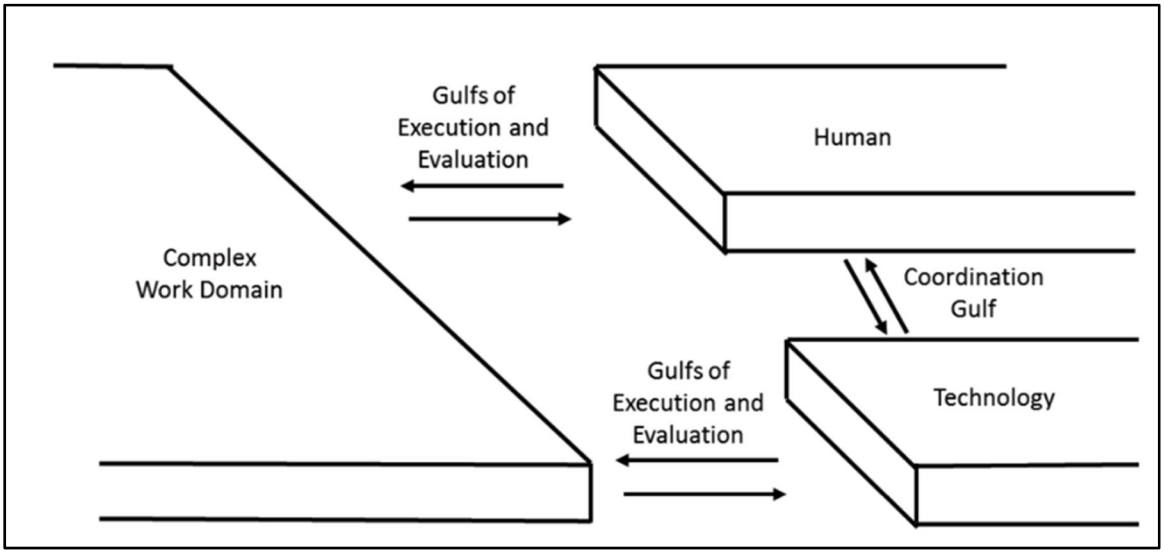

Figure 3. Gulfs of Evaluation, Execution, and Coordination [1]

In essence, a HAI must make the constraints of the work domain salient to the human-autonomy team in a manner that is consistent with the human operator's reasoning capabilities [11]. In Reference 12, Skill-Rule-Knowledge (SRK) framework has been proposed as a method for understanding alternative ways to represent constraints, signals, signs, and symbols, which in turn distinguish three levels of human performance, including skill-, rule-, and knowledge-based [1].

In the context of unmanned vehicle operations, an example of skill-based behavior is an unmanned vehicle operator manually controlling a sensor to keep a moving target in view. The location of the target in time and space provides the operator with the signal, and the goal is to continuously adjust the sensor any time the target deviates from the center of the screen.

In rule-based behavior, an operator has a set of predetermined solutions that are triggered by specific conditions, that is, signs. Figure 4 illustrates rule-based behavior for determining the best search pattern to use in the presence of a specific combination of signs for an unmanned

1989 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

vehicle operator to find a target. For example, if an operator is searching in a nonmountainous region for a target that is likely to still be near the last known location but the target's direction of travel is unknown, a sector search is the best option. These rule-based solutions often help an operator quickly identify a good enough solution [13].

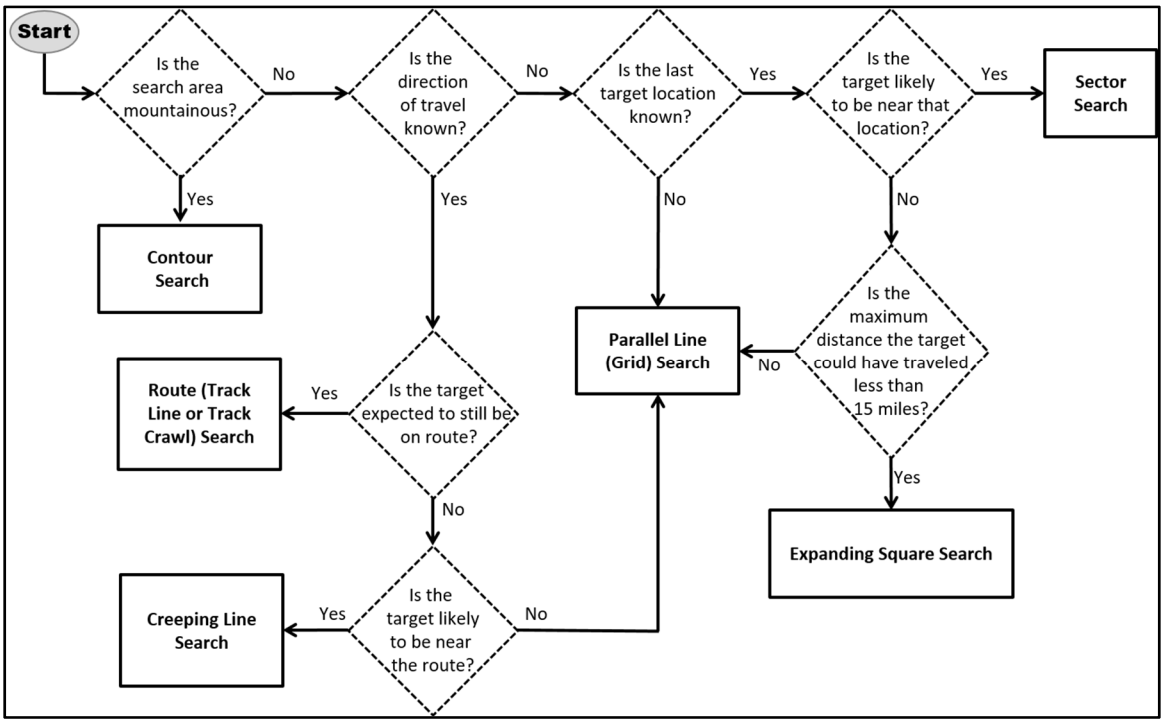

Figure 4. Optimal Search Pattern Decision Tree [13]

Knowledge-based behaviors occur when an operator encounters a novel unexpected situation for which no procedure exists [12]. In these instances, an operator may evaluate and critique skill- and rule-based tactics in order to learn from mistakes, take advantage of opportunities, and avoid threats that arise due to changing situation contingencies. For example, an operator may modify a rule-based strategy to find a target based on their knowledge of insurgent activity in the area or the limitations of the only unmanned vehicle that they have available [13].

Reference 14 developed an HAI that was designed to support rule- and knowledge-based behaviors for operators tasked with managing multiple unmanned vehicles in support of base defense missions. To support rule-based behaviors, interfaces were developed that allowed operators to quickly call high-level plays, which are adaptable plans of action using one or more unmanned vehicle, in response to different mission events. For example, in response to a report of an unidentified watercraft at Point Alpha, an operator can quickly call an Air Inspect play. In response, the IA recommends an unmanned vehicle that can get eyes on the unidentified watercraft in the least amount of time, plans a route for that unmanned vehicle, and monitors the unmanned vehicle's progress as it travels to Point Alpha.

1990 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

By default, the IA will recommend an unmanned vehicle that can reach the desired location in the least amount of time. However, the Play Workbook window allows the operator to provide the IA with information that will help it develop a better plan and change priority variables quickly to see how it impacts the IA's recommendations. For example, the operator can select the size of the target that they are searching for, which impacts the altitude a UAV would search at and/or the zoom level of the sensor. Additionally, environmental conditions that impact the effectiveness of unmanned vehicles, for example, if it is cloudy, an IR sensor might be better than an EO sensor. Since the Play Workbook provides parameters to optimize the plan, the operator can communicate to the IA what needs to be optimized, such as time to objective, fuel use, detectability, presence, crowd control, and/or tracking. With this interface, the operator can quickly tell the autonomy to find the target while keeping a low profile, optimize on time, and consider that it is cloudy.

The HAI also supports knowledge-based behavior by allowing the operator to explore the search space. For example, the Plan Comparison tool allows an operator to quickly determine the best plan based on a specific parameter as well as quickly view the overall quality of each plan based on weightings assigned to each parameter. For example, Plan 1 will consume the least amount of fuel, Plan 2 contains the best assets for deterring possible insurgent activity, and Plan 3 has the best crowd control and tracking capabilities.

In order to successfully bridge the gulfs of execution and evaluation, the user interface must support all three modes of interaction—skill-, rule-, and knowledge-based. Within the aforementioned HAI, extended play-based control was implemented to support a variety of human-autonomy teaming requirements [15]:

- Capturing the operator's intent
- Enabling plays that define the actions of one or more unmanned vehicles to be called or edited
- Allocating unmanned vehicles to tasks
- Routing unmanned vehicles
- Providing visibility into the autonomy's reasoning
- Monitoring play progress [15]

This HAI illustrates the importance of an interface design that supports skill-, rule-, and knowledge-based behaviors so that the human-autonomy team is able to perform not only in familiar events, but able to cope and adapt to unfamiliar and unanticipated events as well.

IV. VALIDATING HUMAN-AUTONOMY TEAMING

The goal of this research is to design HAIs that enable effective collaboration between human operators and autonomous tools to support AMC performance during air assault missions. To achieve this goal, any evaluation must support multiple performance measures in an experimental setting that, to the extent possible, captures and represents the constraints of the natural work domain. Reference 16 calls this type of experimental setting a synthetic task

1991 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

environment. The key is not the physical fidelity of the simulator but how well the research question maps to the properties of the real-world mission environment.

The Future Open Rotorcraft Cockpit Environment (FORCE) simulator, which is a Government-owned and operated simulation environment, contains all the features necessary for a synthetic task environment. An initial set of vignettes was developed by the United States (U.S.) Army Combat Capabilities Development Command (DEVCOM) Aviation & Missile Center (AvMC) Aviation Development Directorate (ADD) to evaluate the impact of TECUMSA on MUM-T missions. A simulation interview technique was used to identify the critical features of each vignette as well as map TECUMSA capabilities to each vignette's mission events.

V. METHODS, ASSUMPTIONS, AND PROCEDURES

A. Methods

Section V.A describes the various Cognitive Task Analysis (CTA) methods implemented during the semi-structured interviews for eliciting knowledge in regard to the general air assault work domain as well as specific AMC tasks.

1. Daily Walkthrough Method

In this portion of the interview, participants were asked to provide an initial, high-level description of their daily job duties as an AMC. The purpose of this segment was to put the participants into a reflective frame of mind and identify potential lines of questioning as the interview continued. The daily walkthroughs provided information about the general sequence of events that occurs upon receiving the operations order and the various considerations that go into air assault mission planning.

2. Task Diagram Method

The goal of the Task Diagram method is to elicit how a particular job is actually performed, not how doctrine prescribes it to be done [17]. In this case, the Task Diagram method was used to elicit the major components of the AMC's job during air assault missions. The interviewers placed a large piece of paper in front of the participants and asked if they could explain the 3-6 major aspects of their jobs as AMC. They were told to draw 3 to 6 circles, and each one would represent a major component of their job. Each component would be labeled, and bullets would be generated in each circle to describe that aspect of the job. Arrows would indicate if the major components were dependent on each other or occur in chronological order.

3. Wagon Wheel Method

The Wagon Wheel method [18] was used to understand the communication channels that exist between an AMC and their surrounding team during an air assault mission. For this exercise, participants were presented with the diagram in Figure 5 and asked to identify each individual the AMC communicates with during mission execution, including the direction of communication flow, which is indicated by the arrows; the information communicated; and the method by which the communication occurs, for example, radio, chat, and so forth. Communication channels that exist for an AMC can vary depending on mission type and

1992 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

available mission support; therefore, participants were initially told to consider including the communication channels that were generally present across a variety of missions and circumstances.

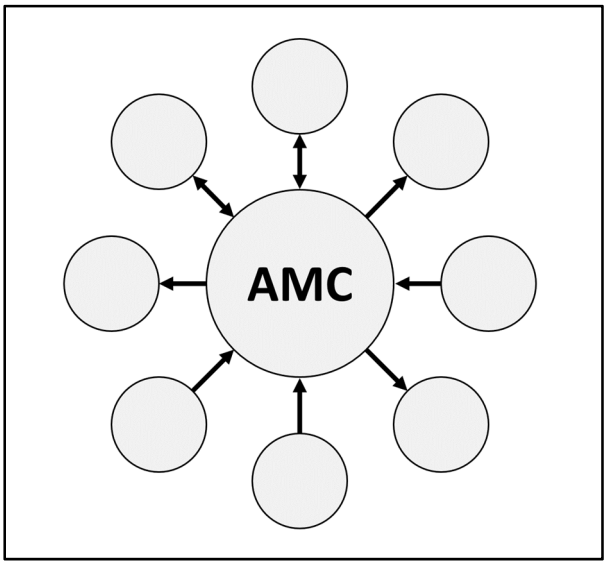

Figure 5. Wagon Wheel Template [18]

For each communication node the participant were asked the following questions [18]:

- What type of information is passed?
- From where did you receive the information you are transmitting?
- From where did they receive the information that was transmitted to you?
- Did you modify the information in any way? Was the information passed in its original form or was it altered, filtered, prioritized, and so forth in any way?
- What decisions does this information affect?
- Could this information be passed in another format, for example, digitally instead of voice?
- How do you know they received the information?
- How do you know when to provide them with this information?
- Would you consider this piece of information to be critical to the team's success?
- What's the impact to the team if this communication line is broken?

1993 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

4. TECUMSA Demonstration Method

For this portion of the interview, participants were given a brief demonstration of the TECUMSA HAI, including the play calling interfaces, plan comparison tool, and vehicle dashboard as well as TECUMSA's autonomous capabilities, including the route planner and IA. Participants were then asked to provide feedback on what they liked, disliked, and found confusing about the HAI as well as what modifications needed to be made to adapt the HAI for air assault missions.

5. Simulation Interview Method

A simulation interview was used to derive the contextualized judgements and decision making processes that experienced AMCs make across a variety of mission configurations and environmental circumstances [19]. For this effort, the simulation interview focused on how each participant would use their ownship and UAVs to accomplish different vignette tasks, for example, reconnaissance, surveillance, overwatch, and so forth. Using a paper and pencil method, SMEs were provided with a map of a battlespace with various terrain characteristics, including mountain ridges, Restricted Operating Zones (ROZs), known enemy locations, dense population areas, Named Areas of Interest (NAIs), a Landing Zone (LZ), and an objective location. Participants were encouraged to brainstorm events, tasks, constraints, and obstacles to include in future scenarios and asked to provide feedback on the fidelity of the vignettes as well as explanations for the courses of action that they considered and the respective optimality for mission success, crew survival, and so forth. Finally, participants were asked to map existing TECUMSA plays to the vignette mission events as well as determine the number of new plays that needed to be developed.

B. Participants

Three veteran Army helicopter pilots with a combination of over 55 years of experience in Army Aviation and extensive combat service as AMCs, as shown in Table 1, were interviewed. All three participants were male with an average age of 46.5 years. Combat deployments included Iraq, Afghanistan, Pakistan, South Korea, and Kosovo.

Table 1. Total Participant Experience

Aircraft	Noncombat Hours	Combat Hours
CH-47D/F Chinook	3500	3000

UH-1H Iroquois	110	
MH-47E Chinook	100	

1994 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

C. Assumptions

The methods of eliciting information from participants will ultimately determine the quality of the information that is gathered. To ensure both breadth and depth of the information received from participants, a broad set of knowledge elicitation methods were utilized to provide sufficient insight into the air assault work domain and the tasks of an AMC. In addition, participants answered all interview questions and knowledge elicitation prompts honestly and had a sincere interest in providing beneficial results.

D. Procedure

Participants were given an overview of the goals of the project, including the design of an intelligent human-autonomy team that can optimally manage multiple Manned-Unmanned (MUM) aerial systems in air assault mission environments, as well as a briefing on the capabilities of TECUMSA's autonomous systems. Basic demographic data, including rank and years of service, were then collected. Participants were also asked about their deployment history, specifically focusing on their experience as an AMC. After collecting this demographic data, interviewers conducted semi-structured interviews using the aforementioned methods described in Section V.A.

VI. RESULTS

A. Understanding Role of AMC During Air Assault Mission

During an air assault mission, the AMC is the leader and final authority of all air assets during the mission. Reference 20 states that "The AMC is the aviation unit commander. He/she receives and executes the Air Assault Task Force Commander's AATFCs guidance and directives, and controls all aviation elements. The AMC ensures continuity of command for all supporting aviation units and employs attack helicopters and artillery along the air route, fighting the battle from Pickup Zone (PZ) to LZ while keeping the AATFC informed." Participants identified three major phases of an air assault that the AMC plays an instrumental role in:

- Planning
- Briefing
- Execution

The final phase of an air assault mission would technically be the debriefing; however, participants suggested that there is not always time available to complete this phase. Figure 6 illustrates these three different phases and includes the primary activities of the AMC during each, according to SME feedback. Using the Task Diagram method, the major phases of the air assault and associated tasks of an AMC during each were identified.

1995 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

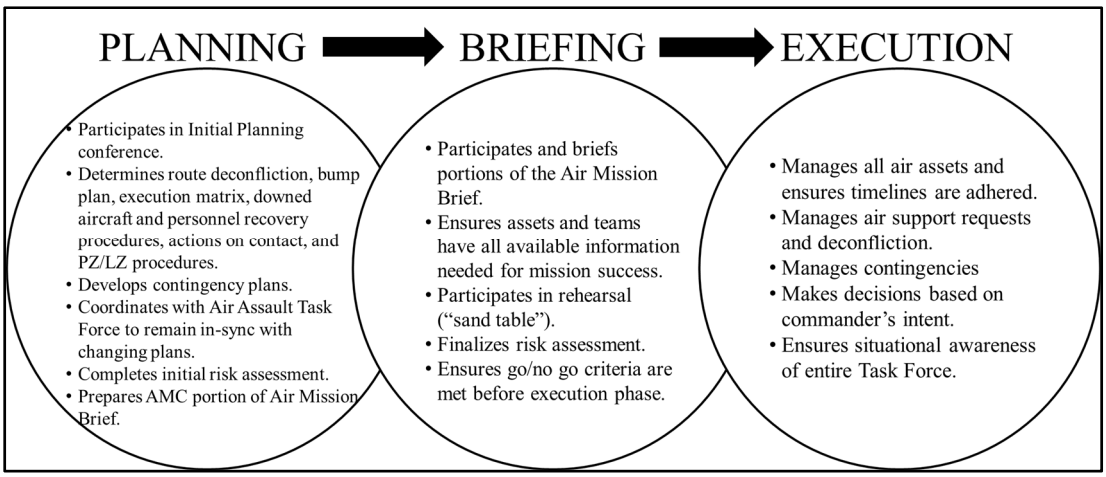

Figure 6. Task Diagram Method

1. Planning

Air assaults are not spontaneously executed. While a mission can be hastily planned for, it will not be unplanned for. The nature of air assaults is not very forgiving. They take place in hostile, unpredictable, and ever-changing environments where the slightest error can carry with it an unforgiving and often irreversible consequence. It is therefore critical that the objective is considered with respect to the desired end state of the battlespace. Therefore, extremely detailed and precise reverse planning that works backwards from the ground tactical plan, or the last stage of mission execution, is completed before the aircraft takeoff to ensure mission success, as shown in Figure 7. Figure 7 shows that air assault planning starts with the desired end state of the Ground Tactical plan and then works backwards, rather than planning in the chronological order that the air assault will actually be executed in. This is known as reverse-order planning. Contingency plans are also developed in the event that if something does not go according to plan, there is a prepared secondary course of action to take.

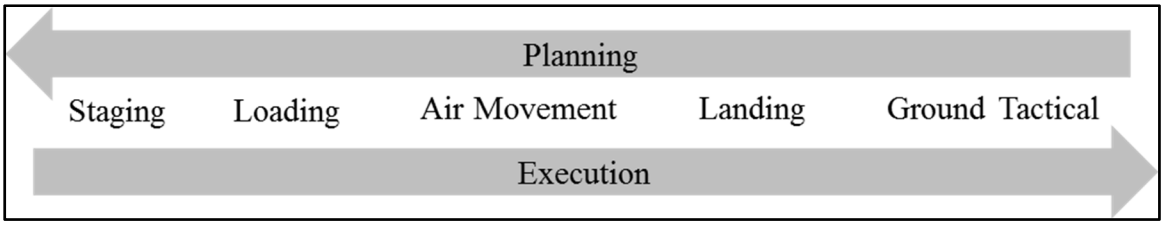

Figure 7. Stages of Air Assault

While the AMC does not lead every step of the planning process, they are considered one of the most knowledgeable personnel and leaned heavily upon for their expertise throughout the planning process. The primary tasks of an AMC during the planning phase include the following:

- Participating in Initial Planning Conference (ICP)—the ICP is an initial meeting between the Air Assault Task Force (AATF) and supporting aviation unit, for example, AMC, liaison officer, and flight leads, where they can address environmental factors, such as climate, weather, terrain,

1996 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

and altitude, which may impact the performance capabilities of the aircraft. The ICP is held as early as possible in the air assault planning process to ensure the crew is adequately prepared to successfully accomplish the upcoming mission.

- Determining route deconfliction, bump plan, execution matrix, downed aircraft and personnel recovery procedures, actions on contact, and PZ and LZ procedures
- Developing contingency plans
- Coordinating with AATF to remain in sync with changing plans
- Completing initial risk assessment
- Preparing AMC portion of Air Mission Brief

2. Briefing

The briefing phase is a critical step to ensure everyone involved in the air assault is on the same page. During this phase, planning should be finalized and only minor changes to the plan should occur. The AMC's role during briefing is to verify that every detail of the mission is accounted for and that the sequence of events will maximize the chance of success while minimizing the risk of losing personnel and/or equipment. The AMC's briefing activities include the following:

- Participating and briefing portions of the Air Mission Brief
- Ensuring assets and team members have the necessary information for mission success
- Participating in mission rehearsal (sand table exercise)
- Finalizing the risk assessment
- Ensuring go/no go criteria are met before the execution phase

3. Execution

During the execution phase, the AMC plays the most prominent role, with duties including:

1. Maintaining situation awareness over the entire battlespace, including aircraft states, mission flow, enemy status, and the Ground Commander's intent
2. Coordination with subordinates and superiors regarding updates and changes to the mission execution status
3. Making executive decisions under extreme time constraints and disseminating these action commands to the fleet of aircraft under their command, for example, whether to engage a newly materialized enemy, whether to recover a downed aircraft

1997 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Primary tasks of an AMC during the execution phase include:

- Managing all air assets and ensures timelines are adhered
- Managing air support requests and deconfliction
- Managing contingencies
- Making decisions based on commander's intent
- Ensuring situational awareness of entire Task Force

At each of these three stages, the crux of almost every decision centers around Mission, Enemy, Terrain and Weather, Troops and Support Available, Time Available, and Civil (METT-TC) factors. Table 2 provides a high-level deconstruction of typical AMC considerations within each METT-TC factor. Note that this is not an exhaustive list.

Table 2. METT-TC Factors

Factor	Typical Considerations
Mission	• Answers to Who, What, When, Where, and Why • Commanders Intent • Desired End State • Concept of Operations • Scheme of Maneuver • Tasks to Subordinate Units
Enemy	• Composition, for example, number of personnel, vehicles, and weapons • Disposition, for example, organization, strengths, vulnerabilities, and tactical mobility • Equipment, for example, armored vehicles, and anti-aircraft artillery • Location • Capacity, strengths and weaknesses • Mission and Purpose • Possible and Probable Courses of Action • Recent Activities and Patterns of Life
Terrain	• Artificial and Natural Obstacles • Avenues of Approach • Advantageous Terrain Features, for example, cover, concealment, and reduced intervisibility • Disadvantages of Terrain Features, for example, affords enemy cover and concealment
Weather	• Wind • Temperature • Visibility • Cloud Cover • Precipitation • Humidity

1998 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

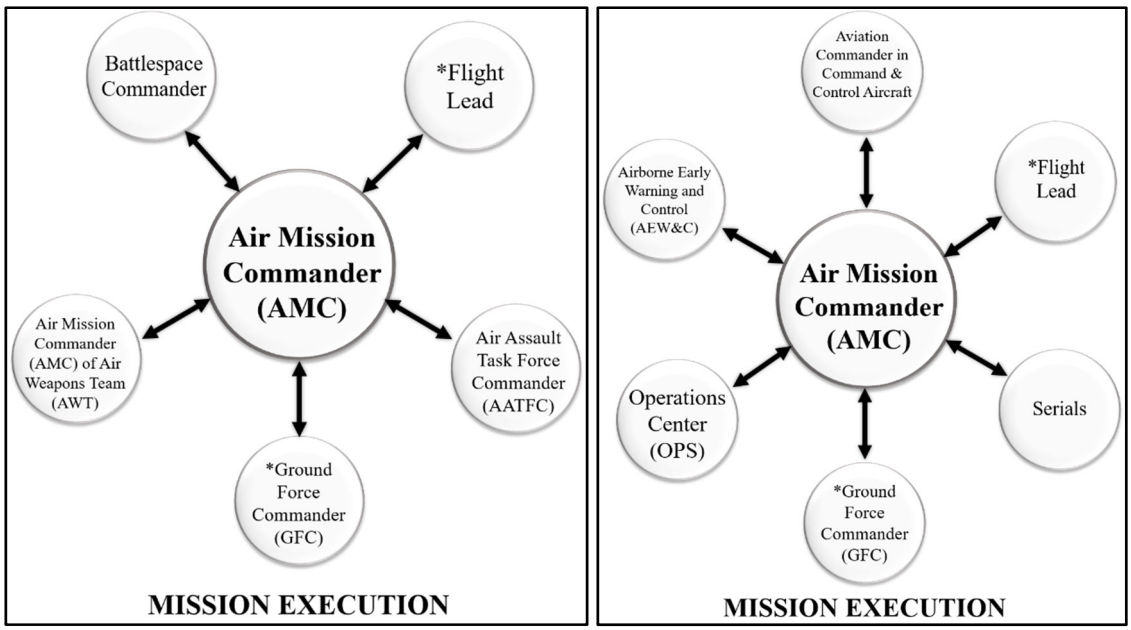

Table 2. METT-TC Factors (Concluded)

Factor	Typical Considerations
Troops and Support	• Number, type, capabilities, and condition of available friendly troops and support. These include supplies, services, and support available. • Crew Availability, for example, crew members require superior's approval to work in excess of 12 consecutive hours and crew strengths guide personnel selection • Aircraft Status, for example, in maintenance • Support Systems, for example, MEDEVAC aircraft available for standby • Combat Resources, for example, finite weapons and fuel onboard
Time	• Planning and Preparation of combat orders, that is, deliberate, constrained, and hasty • Inspection and Rehearsals • Timeline for Movement, for example, PZs, Start Phases, Air Control Points, Release Points, and LZs • Movement: Strict Time Constraints During Air Movement, for example, aircraft are only allowed to be +/- 30 seconds off of the flight plan during air movement
Civil Considerations	• Cultures and Activities • Civil Institutions • Infrastructures and Organizations • Populated Areas

4. AMC Communication

Coordination and communication, particularly before and during mission execution, ensures that command and control is maintained and mission objectives are successfully accomplished. The wagon wheel interview methodology was employed as a tool for taking a brief audit of the main communication channels that exist for the AMC during the air assault execution. Although it is common for the acting AMC of the mission to also be the pilot-in-command of their aircraft, this particular aspect of communication within the aircraft between the pilot-in-command and their aircrew, for example, a copilot or flight medic, was not discussed in detail during the wagon wheel exercise and is therefore not included in the results. Figure 8 contains two completed wagon wheel diagrams that were filled out independently by interviewees. Figure 8 also includes asterisks that indicate a position included in both SME 1 and 2 diagrams.

1999 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

a. SME 1 *b. SME 2*

Figure 8. Wagon Wheel Diagram Filled Out Independently

Noting the similarities and differences between the two diagrams provided a concrete artifact from which to resolve discrepancies during a joint session with participants. Having participants explain and justify the inclusion of each personnel in their diagram helped fully capture how air assault teams communicate. This discussion resulted in the agreed-upon revised wagon wheel shown in Figure 9. The updated wagon wheel diagram includes Contingency Assets (CAs) that are not universally available across every air assault mission but are considered essential elements to include in the diagram. If available, any of the CA support can be requested by the AMC, at which point the AATFC can then temporarily assign the requested CA to support the AMC, thus creating an additional branch of communication with the AMC. Note that the AMC will probably not be the only one communicating with the newly assigned CA. Flight leads, AATFC, Unmanned Aerial Systems (UASs) and Air Weapons Team (AWT), and Ground Force Commanders (GFC) can and likely will all be coordinating directly with the newly assigned CA as well. To facilitate the process of rebuilding a united wagon wheel diagram, participants focused on specific details of SUMIT's Simulation Evaluation Plan training vignettes. For example, the node in Figure 9 labeled UAS and AWT was largely included based on the parameters of the vignette. Although this communication channel, that is, node, is not necessarily uncommon, it is less universal across missions.

2000 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

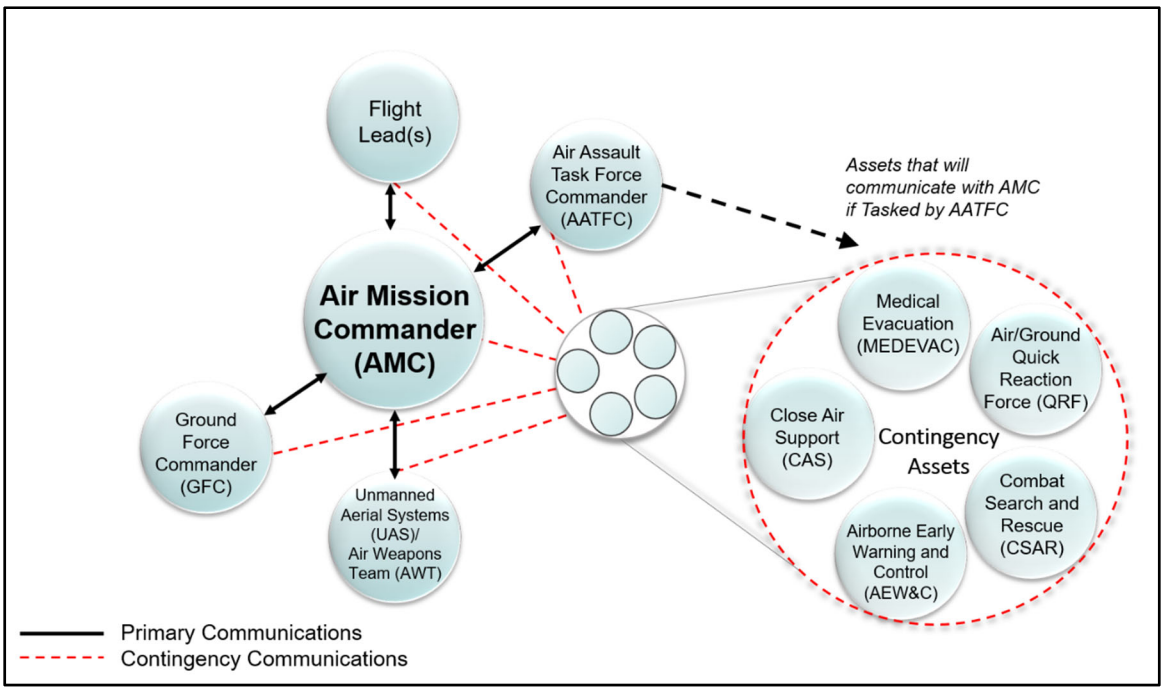

Figure 9. Updated Wagon Wheel Diagram

Table 3 provides more details regarding each communication node listed in Figure 9, including a description of that individual's roles and duties, what information that individual sends to and receives from the AMC, and the method of communication, for example, radio and chat via the tactical internet.

2001 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 3. AMC Communication Channels

Position	Roles and Duties	Communications From AMC	Communications to AMC	Communication Method
AATFC	• Overall commander of the AATF • Ensures continuity of command throughout the operation • Overall responsibility for the air assault operation	• Mission event milestones, for example, Ex-check • Additional support unit requests • Updates and mission changes	• Additional tasking or mission changes • Updates regarding the AMC's requested contingency assets, for example, approval of request and estimated time of arrival for asset	• Radio • Chat
GFC	• Commands largest ground maneuver force inserted during air assault • Usually one of the AATFC's subordinate maneuver commanders • Maintains communication with AATFC throughout operation	• AMC monitors GFCs execution checklist transmission to the AATFC • Mission event milestones - only source of situation awareness for the GFCs	• Requests additional support, for example, surveillance and fire support	• Radio • Chat
Flight Lead(s)	• Navigation • Enroute communication, for example, keeps AATFC updated on flight status • Obstacle and threat avoidance • Monitors energy state of all aircraft	• Mission changes or deviations, for example, route changes • Request for updates and aircraft status	• Flight status, for example, obstacles and threats	• Radio • Chat
UAS and AWT	• Reconnaissance of the route, LZ, and NAIs • Fires and overwatch for ground forces	• Tasking requests, for example, video feed of LZ	• Video feeds • Laser designation data • Target identification data	• Radio to UAS operators • Chat

Table 3. AMC Communication Channels (Concluded)

Position	Roles and Duties	Communications From AMC	Communications to AMC	Communication Method
AEW&C	• Provides airborne radar services and threat detection to give early warning of incoming aircraft or missiles • Assist AMC with airspace deconfliction	• Request for assistance with airspace deconfliction	• Incoming threats, for example, aircraft and surface-to-air missiles	• Radio • Chat
CAS	• Provide ground troops with additional fire support and enemy suppression	• Request for BDA • Request amount of ordinance on board • Request time available on station	• Time to target and response time • BDA reports • Any new threat updates • Weapons status for follow on missions	• Radio

2004 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

B. Participant Feedback on TECUMSA Demonstration

Participants were asked to provide feedback on the original user interface during a brief demonstration of TECUMSA. Participants received introductions to features including the play calling interface and vehicle dashboards as well as TECUMSA's autonomous capabilities including the route planner and IA. In-depth discussions were largely focused on the details in the Simulation Evaluation Plan, prompting context relevant insights into how to better tailor the HAI to assist an AMC during an air assault mission.

1. Map

Participants provided inputs regarding TECUMSA's map display. For example, when asked whether a satellite or topographic map was preferable, participants explained that different information can be gleaned from each. Roads, heavily traveled paths, and possible obstruction and characteristics of the LZ cannot be seen in topographic maps; however, terrain elevation is vague in satellite imagery. Allowing TECUMSA users to switch between or even overlay the two map types would cover the largest range of user needs. Participants also mentioned that it would be beneficial to incorporate Military Grid Reference System (MGRS) into TECUMSA's map display.

2. Icons

Due to the range of aircraft and capabilities in the simulation vignettes, it became apparent that certain distinguishing characteristics should be emphasized in the aircraft icons so entities in the map, vehicle dashboard, and so forth can be easily recognizable. Distinctions and information that participants agreed were valuable to include in the icon design included the following:

- manned versus unmanned
- missile quantity on-board
- current Level of Interoperability (LOI)
- fixed or rotorcraft airframe
- whether the aircraft is ownship, friendly aircraft with LOI, or friendly aircraft but without LOI

While all of these characteristics have the potential to be represented in the icon design, there is a point of diminishing returns where the mass of information will merely serve to clutter the icon and display and confuse the user. Figure 10 shows the original TECUMSA icon representing unmanned fixed-wing aircraft.

2005 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 10. Original TECUMSA Icon Representing Unmanned Fixed-Wing Aircraft

3. Vehicle Status Panel

One participant mentioned the benefit of a weapons summary page to keep track of the quantity and type of armament onboard each of the UAVs available to the operator. Since missiles were not part of the payload previously utilized in the TECUMSA system, the need to represent the quantity and type of missiles onboard each UAV became an HAI requirement. However, with the limited armament considered in the initial evaluation of TECUMSA since only Hellfire missiles are available, the solution concept involved revamping the Vehicle Status Panel into a Vehicle Summary Panel that provides a high-level snapshot of each aircraft's payload information. The Vehicle Status Panel design is discussed further in Section VI.D.3.

4. Vehicle Dashboard

The TECUMSA system includes vehicle dashboards that provide vehicle state information for each vehicle, such as speed, altitude and elevation, payloads, fuel level, sensor status as well as the current sensor feed. One notable suggestion from participants was to have an indicator of the time remaining until bingo fuel, that is, when the UAV needs to return to base to refuel. The participants explained that having this information would be helpful for task management decisions since a blue force overwatch task would be best served by an aircraft that could remain overhead for the entire duration of the overwatch. Participants also suggested that weapon information, such as type and quantity, be added to the vehicle dashboard, again due to the influence this information would have on aircraft assignments and mission planning.

2006 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

5. Airspace Deconfliction

One of the techniques used to elicit participant HAI ideas and feedback was to provide concrete constraints and mission details to reason about during a demonstration of the TECUMSA interface. Based on SUMIT's Simulation Evaluation Plan vignettes, participants were provided a scenario where four UAV's were concurrently in the air and under the AMC's command and control. These were specifically two Gray Eagle (GE) MQ-1Cs, one Shadow (SH) RQ-7, and one Fire Scout (FS) MQ-8. This specific scenario details prompted participants to draw a stack diagram similar to the one seen in Figure 11. This diagram is used as a clear and concise way for air assault crews to visually represent the altitudes of each aircraft flying in the mission and ensure adequate separation. Note at the highest altitude in Figure 11, there is a dashed line representing a lateral separation, which is required since both of the GEs begin the vignette at the same altitude above Mean Sea Level (MSL). This dashed line could represent a predetermined division of the battlespace where GE 1 covers one half of the battlespace and GE 2 covers the other half.

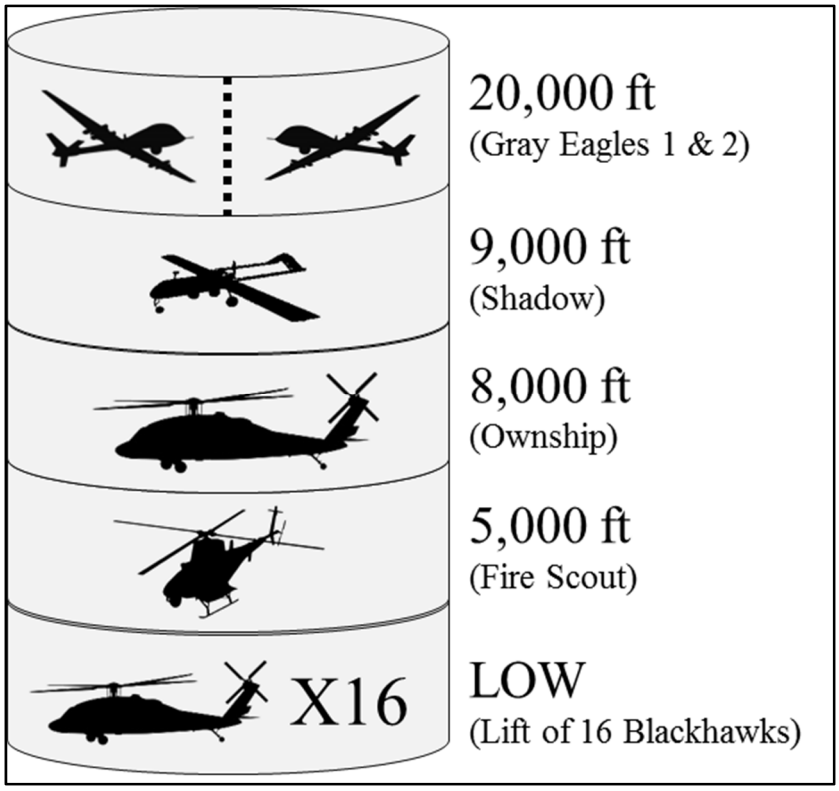

Figure 11. Altitude Deconfliction Stack Diagram in MSL

C. Participant Feedback During Simulation Interview

Developing an IA that can support an AMC during an air assault mission requires understanding the realm of possibility considered by the AMC during a wide range of tasks. The simulation interview technique was used to elicit the step-by-step decision making that a veteran AMC would make across a variety of different scenarios. Example questions included the following:

2007 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- What would you do if an enemy was found behind this ridge?
- What route would you take if a ROZ was called along this section of your current lift route?
- How would this dense population area effect your decisions?

Think-out-loud procedures provided explicit data regarding veteran AMC's thought processes, reasons for action selection, combat strategies, situation assessments, and critical cues to look for. Participants identified how they would complete each of the Intelligence, Surveillance, and Reconnaissance (ISR) tasks listed in Table 4 while utilizing a fleet of up to two manned and four unmanned aircraft. The results of the simulation scenarios were used to guide future TECUMSA play development and optimization parameters for the IA to reason about, for example, an additional play for engagements that optimizes aircraft selection for combat power. For example, participants indicated that the ability to hover could be valuable for certain tasks or in certain environments since in mountainous terrains, a fixed-wing UAV that needs to loiter may have its sensor obstructed by the terrain at various times during the loiter. In contrast, a rotorcraft could avoid these obstructions by hovering in place.

Table 4. TECUMSA's IA Feedback

Vignette Event	Optimization Parameters(s)	Optimal Vehicle	Play	Priority (Order of Operation)
Conduct Renaissance at LZ Direwolf	1. Undetected 2. Sensor Capability	Ownship	Rout Inspect	2
Conduct Renaissance at Axis Mormont	1. Undetected 2. Sensor Capability	SH	Point Inspect	1
Renaissance NAIs	1. Sensor Capability	GE	Parallel Search	3
Overwatch Friendly Forces	1. Combat Power	FS	Air Overwatch	4
Locate Militia Vehicles and Engage if Positive ID	1. Combat Power 2. Laser Capabilities	Depends Where Found	Engage (1 Aircraft Designates and Engages)	*
Surveil Possible Militia Compounds	1. Undetected 2. Sensor Capability	Depends Where Found	Point Inspect	*

Table 4 summarizes participant feedback regarding TECUMSA's IA. Note that an asterisk in the priority column indicates a subtask that would be accomplished during the prioritized tasks.

2008 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

During the simulation interview session, participants were asked to provide feedback on the evaluation scenarios and asked if anything in the scenarios needed clarification. Sections VI.C.1 through 7 are a sample of the questions participants asked during the simulation interview, along with implications for the IA's logic and future scenario design.

1. What are the weather conditions along the route and at the LZ? Are there clouds?

After further probing, these questions revealed the importance of weather considerations for planning and executing an air assault. For example, the aircraft may need to land into the wind depending on how strong the winds are and how experienced the pilots are. If landing into the wind is too difficult or unfeasible, it may require deferment to the alternate LZ. Aircraft sensor capabilities are also affected by weather conditions. For example, in foggy or hazy conditions, an IR sensor might be required for reconnaissance of the ingress route, which may not be a capability of any available aircraft and could require a contingency asset to be requested or a task to be reassigned.

The implication is that the sensor type, for example, EO and IR, should remain an optimization parameter that the operator can select to narrow the search space for the IA to optimize vehicle assignment during play calling.

2. Is it day or night?

There are advantages and disadvantages to both. While day operations are easier to operate aircraft in, there is also an increased risk of enemy fire since the air assault is more visible in daylight. Night operations have the advantage of reducing enemy fire risks but also increases the risk of blue force operator errors and friendly air collisions. Other factors also contribute to whether day or night is preferable, such as the skill levels of the pilots, forecasted weather conditions, and the error tolerance of aircraft movability by the specific characteristics of the LZ.

The implications presented supports the preservation of the sensor type optimization parameter, for example, EO and IR. Furthermore, in the future, default settings for the IA could be set so that in night operations, UAV's are set to fly with higher lateral and vertical separation to avoid collisions that could be particularly beneficial in instances where the AMC chooses to manually fly a UAV.

3. What is the purpose of the dead cow in the LZ? Is it an obstacle?

Participants suggested that power lines or an antenna are more common obstacles. There are even cases when enemy forces have erected power lines in anticipation of an incoming air assault.

The implication is that there is an endless array of obstacles and threats that can be used to evoke a variety of responses from participants during system evaluations; therefore, it is prudent to build simulation scenarios that span both the common and atypical events to promote the development of an adaptable system.

2009 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

4. Is there an alternate LZ or just the one?

Participants pointed out that there would typically be an alternate LZ for the lift aircraft to land in so that if the risk of landing in the primary LZ was too high, they could defer to the alternate LZ. For example, if enemy forces appeared in or around the primary LZ, or a suspicious foreign object materialized soon before the lift was scheduled to land. While the alternate LZ will not always be used, part of contingency planning is to ensure that foreseeable risks are prepared for. As such, if the terrain affords it, a secondary LZ will be included in the landing contingency plan.

The implication is that in the future, TECUMSA's IA could be capable of alerting the AMC of newly detected entities found within the primary or alternate LZs within x minutes of the lift's arrival. In addition, customizable scheduling of play execution, for example, execute a Point Inspect of the primary LZ in 15 minutes, and task reminders, for example, a reminder to call a Point Inspect of the alternate LZ in 20 minutes, are in development. This would allow the AMC to offload some of the task and time management workload onto the TECUMSA system, which can be particularly valuable when nearing the arrival of an incoming lift.

5. When during the vignette should the AMC engage positively identified enemies?

Engaging enemy targets is done very strategically in air assaults. Participants interpreted the vignette details to mean that any positively identified enemies are to be engaged at any point during the 30-minute vignette. However, based on their experience, participants would avoid engagement in the LZ until the last possible minute before the lift arrives in order to preserve the element of surprise and avoid giving nearby threats time to prepare for the lift's arrival. One participant recalled a time where the LZ was cleared and enemies were kinetically engaged just 30 seconds prior to their aircraft arriving in the LZ area. A similar strategy to delay enemy engagement can be applied to enemies along the ingress route; however, target engagement can be unnecessary altogether since changing a route is typically easier than changing a LZ.

The implication is that similar to the actions the IA takes with ROZs, the IA could suggest a re-routed ingress path for the lift to take once hostiles are identified, thus minimizing risk of enemy fire.

6. What is considered PID?

Participants requested clarification of what constitutes Positive Identification (PID) of enemy forces. For example, is it an individual in a uniform, the presence of a weapon, or suspicious activity, such as multiple military-age figures moving in a tactical formation or digging by the roadside?

2010 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The implication is that if Automatic Target Recognition (ATR) is integrated into TECUMSA, these types of cues and engagement rules will be important to train the system on.

7. What are the highest altitudes that can be flown by each aircraft to still provide the ATR with usable sensor data to spot a militia compound and an anti-aircraft artillery system? How large of a field of regard is available for each aircraft's sensor, that is, how much area can each aircraft reconnaissance?

This question revealed a strategy for surveying large areas with a limited number of aircraft. The participants suggested that they would plan the mission so that they could assign a high altitude UAV to be positioned central to multiple NAIs. If the sensor on the UAV could provide usable video feed at a high altitude, this strategy would allow the AMC to survey multiple NAIs at once, exemplifying an experienced mission planner's strategy to always optimize the number of tasks achieved and the amount of resources required.

The implication is that there are certainly more and less optimal aircraft allocation and tasking strategies; therefore, in the future the IA could consider variables, such as area of coverage in the logic for recommending vehicles to fulfill operator play calling.

D. Generating Human-Autonomy Interface to Support Air Mission Commander

Sections VI.D.1 through 7 describe solution concepts based on participant feedback on TECUMSA's HAI components, including updates to the vehicle dashboard, vehicle icons, Play Calling Tile, and Play Workbook, as well as an initial design for a possible airspace deconfliction tool. However, interface concepts described within Section VI.D may be adapted and revised as TECUMSA development progresses.

1. Map

Figures 12 and 13 are screenshots of a portion of the current TECUMSA map display that provides the operator with a pan-, tilt-, and zoom-able map that can be tilted to a 2 ½ dimensional view, which is rendered using Digital Terrain Elevation Data (DTED). Figure 12 includes a bird's eye view of the terrain in TECUMSA's map as well as three UAVs and their corresponding sensor footprints. The user is able to cursor over any spot on the map and get the latitude and longitude decimal coordinates as well as elevation at that location. All known aircraft are represented on the map at all times. Note that the UAV icons used in the map were designed as Two-Dimensional (2-D) images and that modifications may be needed to improve the discriminability from a tilted 2 ½ dimensional vantage point, as shown in Figure 13. Sensor footprints can be seen projecting out from GE2 and FS1 in Figure 13. Note that Figure 13 was taken at a different time than the image in Figure 12.

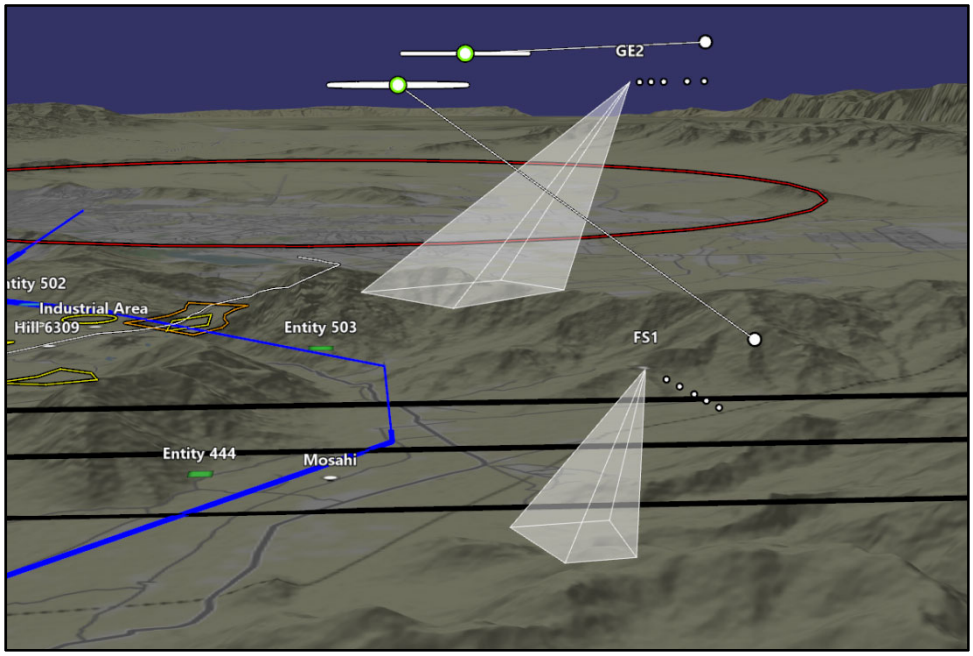

Figure 13. 2½ Dimensional Vantage Point of Terrain in TECUMSA's Map

2012 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

2. Icons

Figure 14 shows a sample set of icons for a Blackhawk Utility Helicopter (UH) 60 (ownship), GE MQ-1C, FS MQ-8, and SH RQ-7. As these icons are based on the actual aircraft, characteristics such as fixed-wing versus rotorcraft are inherently represented in the design. The narrow black cylindrical shapes attached to the sides of the aircraft icons represent Hellfire missiles. The SH RQ-7 is the only aircraft that does not carry missiles. Furthermore, the number of missiles attached to each vehicle icon updates as they are fired, creating direct perception of the aircraft's current payload, as seen in Figure 15.

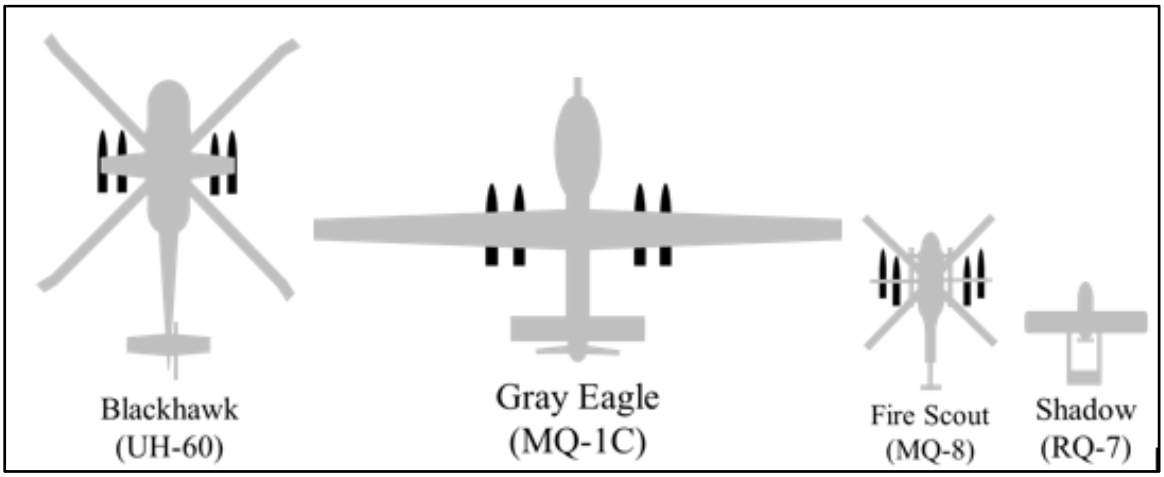

Figure 14. Aircraft Icon Design With Number of Missiles Seen in Black

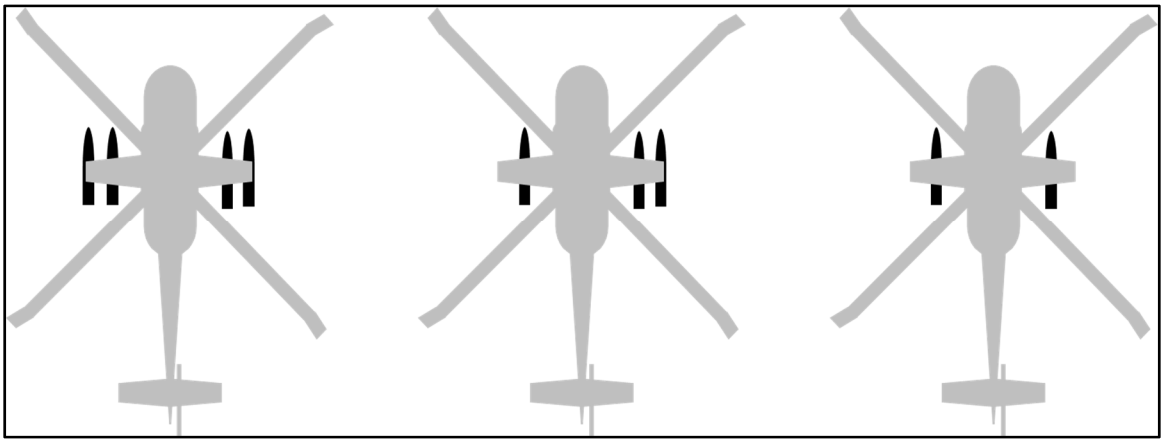

Figure 15. Icon Updating as Missiles are Fired

Figure 16 is an anticipated design that includes features indicating laser designation status, current LOI, aircraft error notification, and play assignment status. For example, after calling a point inspect at Point Charlie, the vehicle changes its course of action and the icon for the assigned aircraft changes from gray to orange. After revisiting this proposed design, it became clear that the LOI value that is depicted in the anticipated design would be illegible when the aircraft icon is scaled down to fit the TECUMSA map, as shown in Figure 12. In addition to being illegible, there is potentially more informational value when the LOI is communicated in terms of functionalities associated with that LOI as opposed to a mere

2013 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

numerical value. Sections VI.D.3 and 4 will cover the graphical representations, that is, icons, for the associated functionalities at a particular LOI.

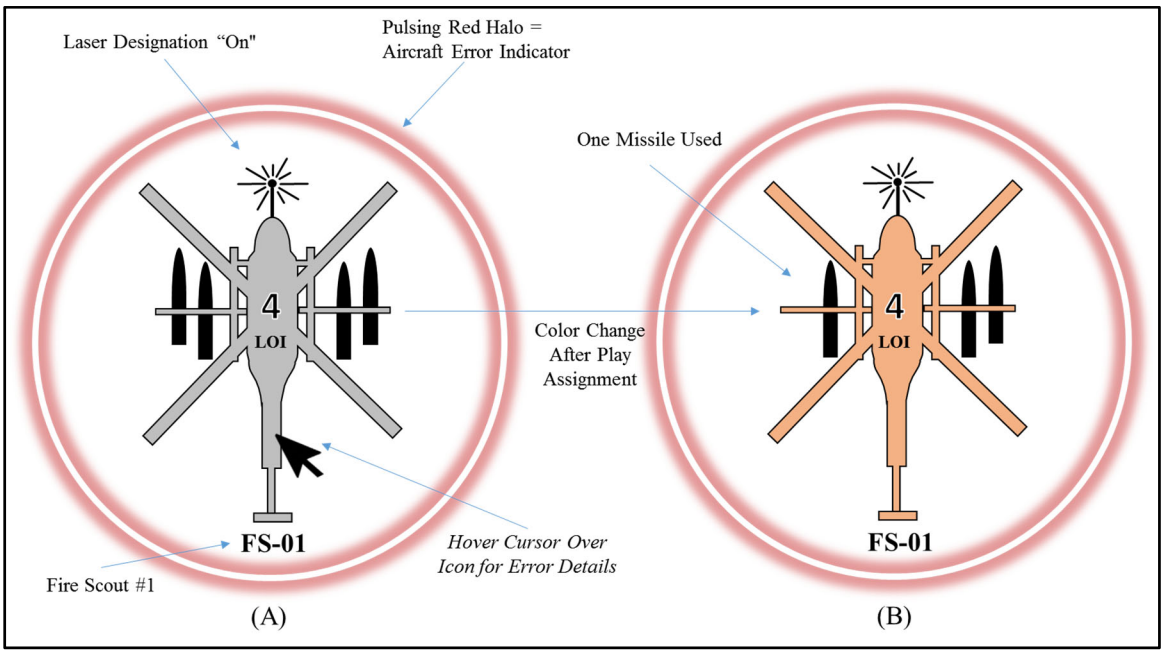

Figure 16. Conceptual Design for Aircraft Icon and Status Features

3. Vehicle Summary Panel

Based on participants' desire for more detailed weapon information, TECUMSA's Vehicle Summary Panel, as shown in Figure 17, was updated to provide a high-level snapshot of each available aircraft as well as the number of missiles onboard, laser designation status, and functionality associated with each aircraft's LOI. The row of icons in each aircraft in Figure 17 are designed to quickly communicate to the AMC what functionalities are available based on the current LOI. For example, the row of icons under the leftmost vehicle (GE-01) indicates that sensors, weapons, and aircraft are all controllable by the AMC. The white fill or background of an icon indicates that the operator has control over that feature, whereas a dark gray or transparent background indicates receipt and transmission of that features data. For example, the operator can view sensor feed but cannot steer it. From left to right in Figure 17, the first UAV (GE-01) has LOI 4, SH-01 has LOI 2, FS-01 has LOI 4, and GE-02 has LOI 3. A potential feature may be added to allow the AMC to have the vehicles sorted and ordered from left to right based on LOI, number of missiles onboard, recency of use, or some other variable. Note that there are pros and cons to having fixed versus dynamic positioning, which can be more thoroughly explored during TECUMSA's HAI testing. In addition, future development efforts may be dedicated to making the LOI icons actionable buttons. For example, clicking the mortar icon opens play calling options where weapons are required.

2014 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

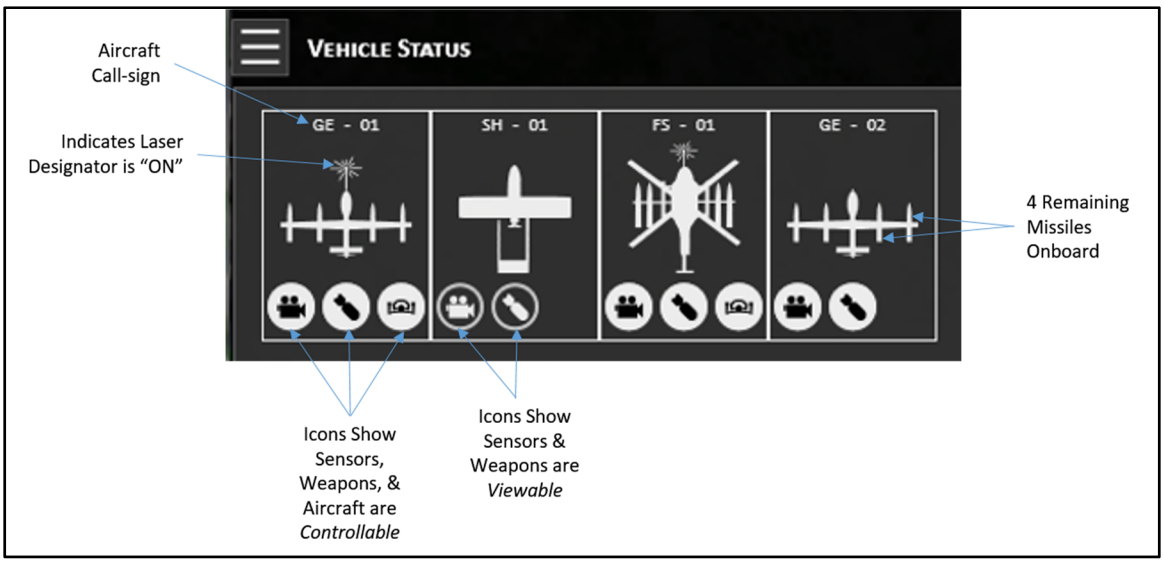

Figure 17. Vehicle Summary Panel Offers Details of Each Aircraft

4. Vehicle Dashboard

Revisions to the vehicle dashboard were made based on the SME's feedback. Figure 18 shows the modified vehicle dashboard display, which includes the following:

- Call sign of aircraft
- Laser Designator Status
- Numerical LOI value as well as icons representing features associated with that LOI
- Fuel Gauge - percentage of remaining fuel
- Low Fuel Icon
- Knots True Airspeed
- Altitude
- Available Sensors on the aircraft
- Remaining Hellfire Missiles onboard
- Station Time - a countdown clock indicating the remaining time before the aircraft reaches Bingo fuel and must return to base, which is a dynamic value since it depends how far away the aircraft is from base.

2015 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

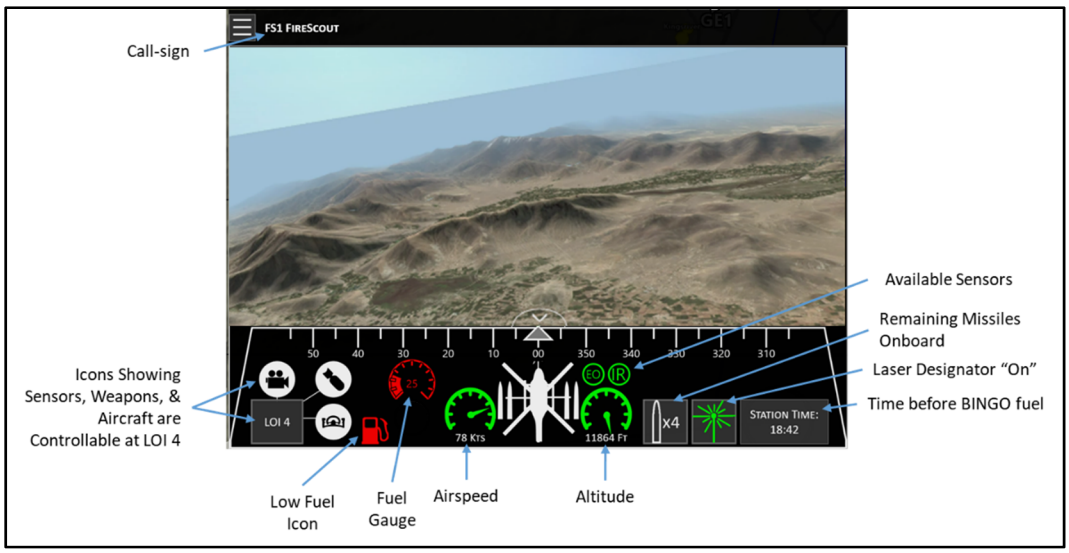

Figure 18. Vehicle Dashboard

Additionally, during a hostile entity engagement, the vehicle dashboard of the engaging aircraft provides a missile release confirmation to the operator, as shown in Figure 19. Providing this information in the sensor feed of the engaging aircraft allows the operator to maintain situation awareness over the unfolding battlespace, both minimizing the probability of casualties and preserving positive identification of the target. The availability of the Fire Now button is context sensitive and is only available once the engaging aircraft is within range of missile release, for example, less than or equal to 9 kilometers (km) slant range.

Figure 19. Vehicle Dashboard Confirming Missile Release During Target Engagement

2016 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Once the Fire Now button is selected, a secondary safety popup appears so that the operator can either confirm or cancel the missile release. Although a subtle design detail, the decision to have an additional input from the operator to confirm weapons release was deemed essential. Popups that require operator input should be implemented cautiously as they can be jarring to a user and can pull attention away from potentially more important tasks occurring at the time. However, in this case, the cost of an additional operator input is greatly eclipsed by the consequence of an unintended and irreversible user input that has a high probability of resulting in a casualty event.

Additional changes may be made to the vehicle dashboard later in the development process to allow quick access to information regarding the diverse set of onboard weapons, for example, cursor hover-over text and/or expandable Weapons Information page. Future updates may also allow an operator to directly manipulate certain features in a vehicle's dashboard, such as the desired units, for example, switching altitude from meters to feet or fuel from liters to pounds. Other features may be added, such as a fuel bug marker on the fuel gauge that informs the operator of the Bingo fuel level, as shown in Figure 20, or another countdown timer that indicates how long an operator has control over a particular UAV. The countdown timer would be beneficial in situations where control of the asset is time limited. It may be helpful to think of there being operator station time with an aircraft as well as global station time and the latter being independent on who has control over the aircraft. Figure 20 shows the fuel bug updates throughout the flight from A to D that reflect the amount of fuel needed for the aircraft to return to home base.

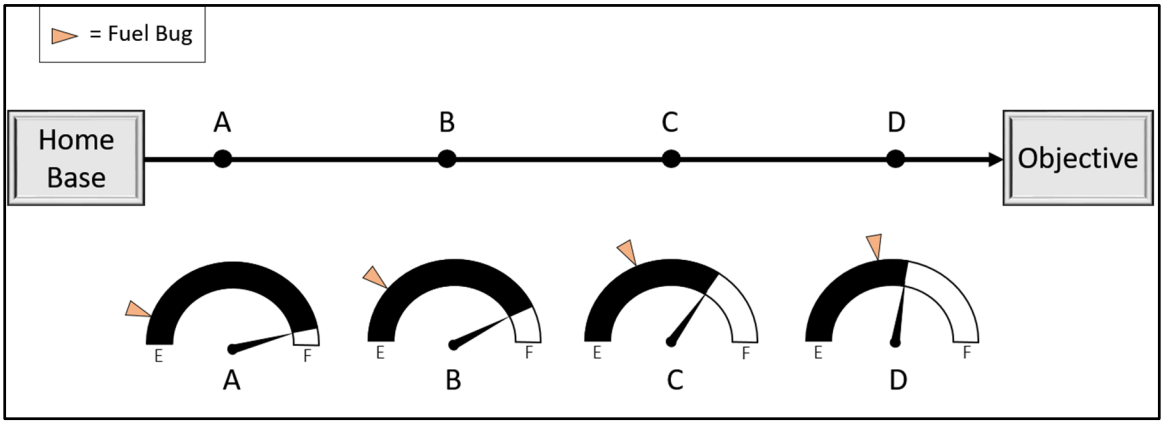

Figure 20. Dynamic Fuel Bug or Bingo Fuel Marker

5. Airspace Deconfliction

Figures 21 through 23 show three airspace deconfliction tools that are designed to provide an AMC direct perception of the occupied airspace and direct manipulation capabilities as a means to quickly manage and correct impending problems via drag-and-drop capabilities. Used in coordination, the tools are expected to prove instrumental for unmanned-manned teaming operations where a single operator is in charge of maintaining situation awareness over multiple aircraft in the same airspace.

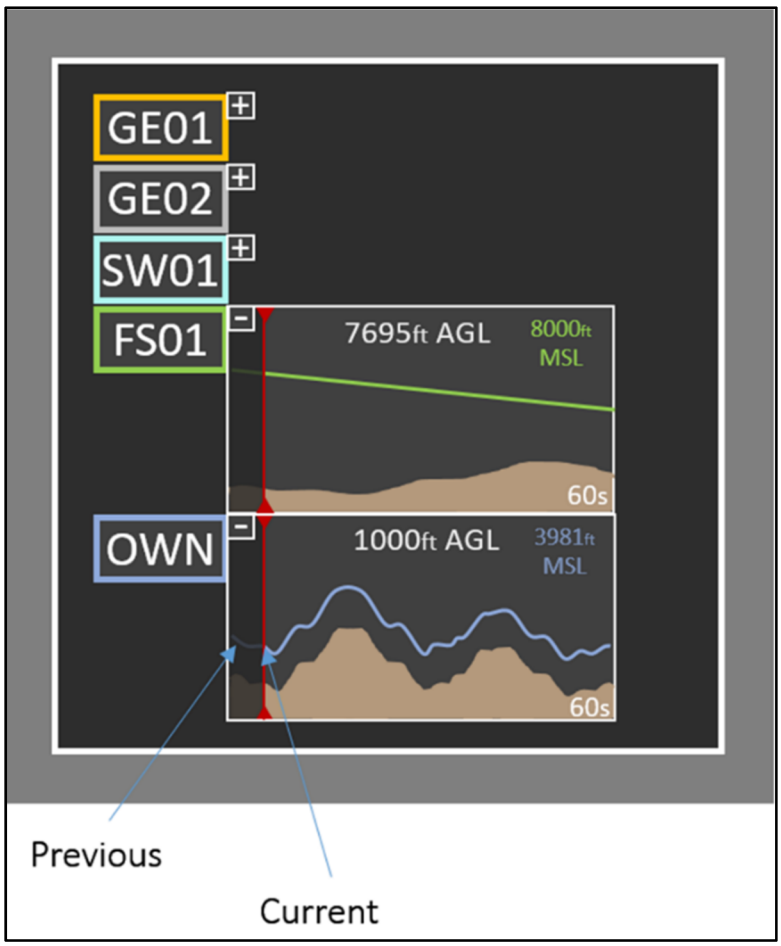

Figure 22. Individual Altitude Management Tool

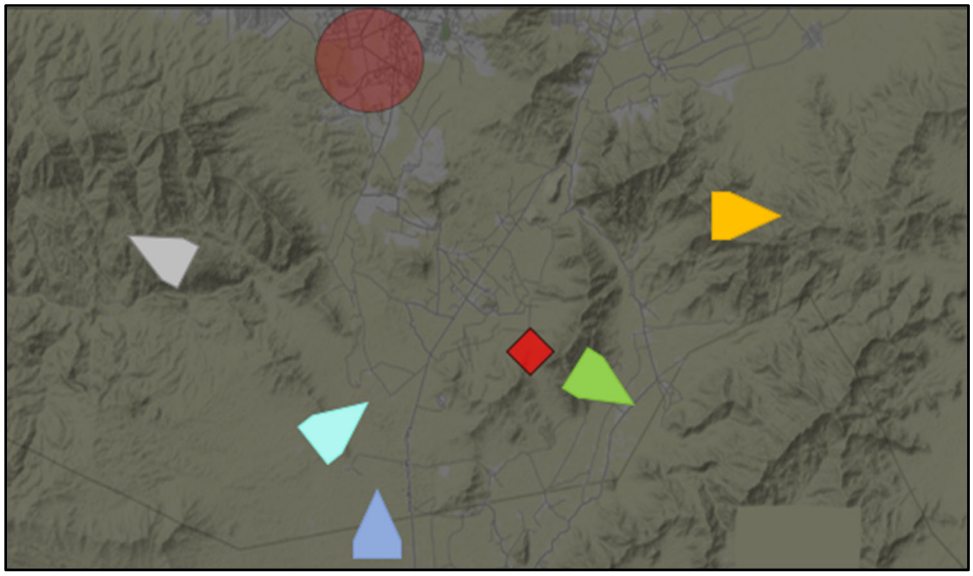

Figure 23. Abbreviated Map

2019 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 21 illustrates the Fleet Altitude Management tool, which includes the current altitudes in MSL of all known aircraft in the airspace, projected altitudes of these aircraft in the next 60 seconds, and commanded altitude if an aircraft is directed to ascend and descend. The scale range of the display dynamically adjusts to include the highest and lowest altitudes of the represented aircraft, and the projected altitude is designed to be operator-adjustable, for example, 60 and 120 seconds. The color of each aircraft is consistent with the color coding observed in all other displays, for example, Vehicle Summary Panel, aircraft icon in the map, and vehicle dashboard, as a way to manage situation awareness of aircraft that are actively executing plays.

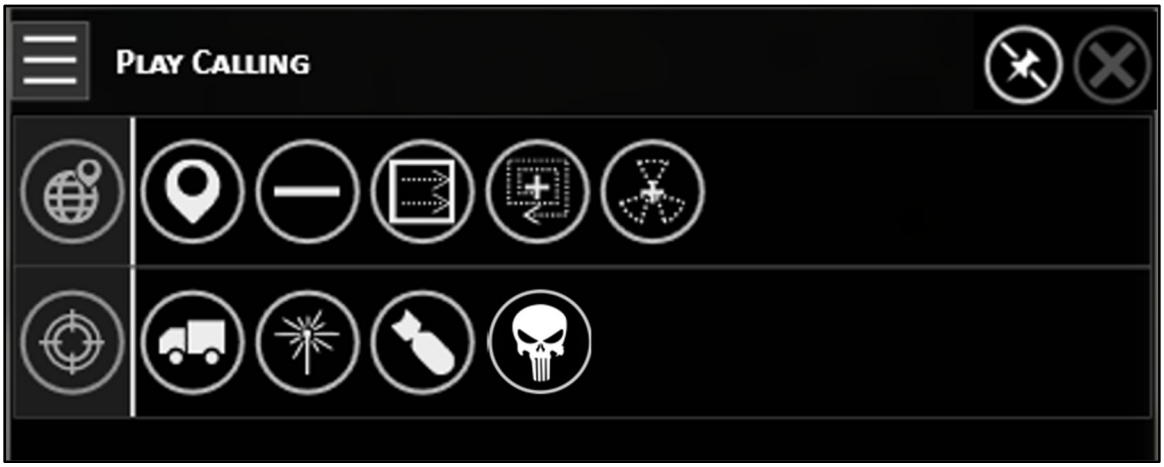
A drag-and-drop feature is intended to allow the operator to quickly move an aircraft's call sign box to the desired altitude. Once set, the aircraft begins to descend and ascend to the newly commanded altitude. Figure 21 shows that the newly commanded altitude for FS-01 is set to 5,000 feet (ft), and after 60 seconds of descending, FS-01 is projected to be flying at just below 7,000 ft. This tool could also allow the operator to hover their cursor over a particular aircraft's call sign box to see additional flight information, such as the altitude Above Ground Level (AGL) and ascent and descent rate.

Using the Fleet Altitude Management tool, the operator can quickly determine if there are any current or near-term airspace conflicts between aircraft. In addition, context sensitive warnings can be tied in to warn the operator of possible problems. A sample of the warning conditions that the autonomous system could be programmed to look for include aircraft violating a minimum vertical separation of 500 meters, an impending collision between aircraft based on altitude and heading, an aircraft that is violating or going to violate a ROZ, and/or an aircraft that is in range of a known hostile.

Representing aircraft altitudes in MSL ensures a stable reference point, that is, the average MSL, allowing an operator to easily know where the aircraft are relative to one another. If the FS is at 8,000 ft MSL and the ownship is at 4,000 ft MSL, the operator immediately knows that there is 4,000 ft of vertical separation between them. However, only having altitudes in MSL can become problematic, particularly when aircraft are flying at lower altitudes in mountainous areas. The Individual Altitude Management tool was therefore designed to provide the operator with information regarding an aircraft's position relative to the terrain, emphasizing the AGL altitude, as shown in Figure 22.

Only the FS and ownship's displays are opened in Figure 22. SME's indicated that having the individual displays with terrain information might only be useful for certain aircraft at certain times, so a collapsible display for each aircraft provides the capability to reduce unnecessary clutter when it is not needed by the operator. There is also the MSL altitude indicated in the individual aircraft displays to make pertinent information available across both of the altitude management tools.

Although the Fleet and Individual Altitude Management tools provide a comprehensive view of the vertical airspace, there remained a concern of being able to quickly communicate the lateral separation between aircraft. A task saturated operator may want a quick representation of the battlespace without the need to pan and/or zoom the TECUMSA map. Figure 23 illustrates the idea for an abbreviated map display that offers the operator a small



2020 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

decluttered version of the full TECUMSA map. This would provide the operator with an updating top-down snapshot of the critical elements for airspace management. The abbreviated map in Figure 23 shows the current location and heading of each known aircraft (irregular pentagons) as well as the location of a ROZ (red semi-transparent circle) and a known hostile entity (red diamond).

6. Plays

Participants provided feedback on the existing play calling interface, identifying existing plays that would be relevant to air assault missions and suggesting new plays that need to be developed. Based on this feedback, Figure 24 shows a revision of the play calling interface was developed that contains two rows of plays. The top row contains location-based plays, including the following from left to right:

- Point Inspect—UAV travels to a point and hovers and loiters with its sensor focused on the point.
- Route Inspect—UAV travels along a route with its sensor focused on the route.
- Parallel Search—UAV searches a specified area using a bidirectional raster scan search pattern.
- Expanding Square Search—UAV searches around a specified point using an expanding square search pattern.
- Sector Search—UAV searches around a specified point using a sector search pattern.

- *Figure 24. TECUMSA Play Calling Tile*

2021 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The bottom row contains target-based plays and from left to right:

- Overwatch—UAV continuously updates its position to ensure its sensor is on a target. The route planner will adjust appropriately according to the type of target, for example, friendly, neutral, unknown, or hostile.
- Designate—UAV continuously updates its position to ensure that it is successfully lasing a target.
- Engage—UAV uses a weapon to engage a target.
- Remote Engage—A dual-UAV play where one UAV laser designates the target and a second UAV engages it.

In addition to these plays, a possible multi-vehicle play was identified which would task multiple UAVs to search multiple NAIs or Points of Interest (POIs)

7. Optimization Parameters

Based on SME feedback, the optimization parameters in the Play Workbook were modified to the parameters shown in Figure 25 in order to capture the parameters most vital for air assault missions. The optimization parameters include from left to right:

- Speed—time to reach the play location and target
- On Station Time—duration on task before needing to be refueled
- Low Observable—remain undetected
- Combat Power—maximal firepower
- Sensor Capability—range of sensor
- Laser Designation Capability—range of laser

Figure 25. TECUMSA Optimization Parameters

Figure 26 shows additional Play Workbook modifications to allow the AMC to specify the desired fixed-wing or rotorcraft airframe, required EO or IR sensors, and need for weaponry, whether or not missiles are required. Due to the nature of certain plays, some parameters could be automatically disabled. For example, the engage play would disable the no weapons required option since an engage play could not be executed without at least one missile.

2022 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 26. Airframe, Sensor, and Weapons Parameter

E. Validating Human-Autonomy Team

In order to validate TECUMSA's ability to support an AMC during air assault missions, TECUMSA will be tested in a realistic test environment using a variety of scenarios and tasks. AMC SMEs provided valuable inputs on SUMIT's Simulation Evaluation Plan, which was largely focused around increasing the ecological fidelity of the vignettes, as shown in Section VI.B. However, no matter how well the properties of the real world are mapped to the synthetic task environment, capturing all of the variables, constraints, events, and unpredictability that an AMC can experience during an air assault is a monetary and temporal investment that few can afford.

For that reason, TECUMSA has been designed to allow the user to finish the design or adapt to scenarios that TECUMSA may or may not have been planned for. TECUMSA is capable of allowing the operator the full spectrum of control, as shown in Figure 27, where the operator can:

- Manually pilot the UAVs
- Work collaboratively with the autonomy, where the user issues high-level commands and the autonomy carries out lower level tasks such as route planning
- Let the autonomous tools in TECUMSA automatically respond to events and re-routing requirements, for example, re-routing an aircraft to avoid a pop-up ROZ

2023 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

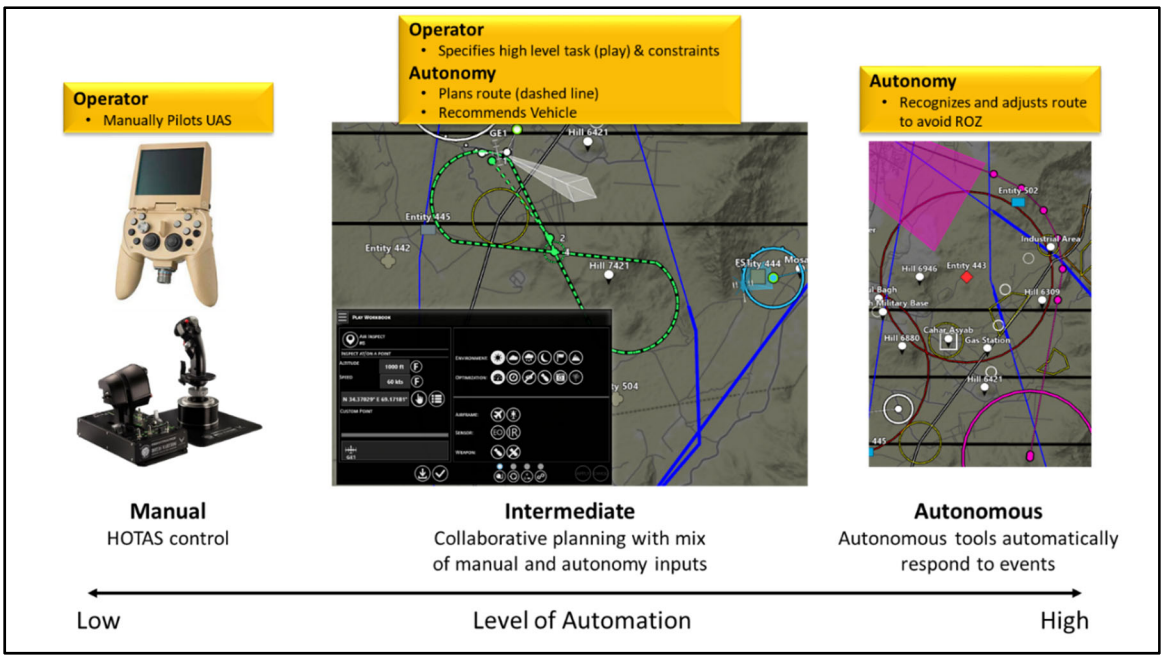


Figure 27. TECUMSA's Spectrum of Control Ranging From Fully Manual to Fully Autonomous Control

This spectrum of control is designed to enable the effective collaboration that is critical to the success of human-autonomy teams, especially in the context of complex sociotechnical systems.

VII. RESULTS AND DISCUSSION

The importance of collaboration between a human-autonomy team was central to the goal of this research. Therefore, this research followed the process of understand, generate, and validate framework employed by Reference 4 in order to develop an HAI that supports an AMC controlling multiple unmanned aircraft in the context of an air assault mission. The CWA revealed the complexity of the domain possibilities along with the boundaries on action. CWA methods using information from Army doctrine and SME interviews provided an understanding of the processes and procedures in an air assault, uncovered the general composition of an air assault team, and identified the specific tasks and duties of an AMC. The CWA began with defining the sequence of events in air assaults, that is, planning, briefing, execution, and the associated tasks of an AMC during each, for example, develop contingency plans, finalize risk assessments, and ensuring timeline adherence. Subsequently, the wagon wheel exercise was used to uncover the communication and coordination that occurs between an AMC and their surrounding team members during mission execution.

2024 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

In order to generate an HAI that supports AMC performance across a range of air assault missions, TECUMSA's current autonomous capabilities were demonstrated to expert AMCs. They provided feedback on TECUMSA's HAI components, including the play calling interface, Play Workbook, and vehicle dashboard. This feedback was used to tailor existing HAI components to support air assault missions, for example, adding laser designation capability and combat power to the Play Calling Workbook optimization parameters, as well as adding new HAI components, for example, airspace deconfliction tools.

An additional goal of this research effort was to provide feedback to SUMIT's evaluation team on their proposed simulation evaluation plan. Participants generated an extensive list of questions, clarifications, and comments in response to a simulation interview in which they were guided through each simulation plan vignette. This feedback not only helped strengthen the fidelity of the simulation evaluation plan, but it deepened the team's understanding of the complex work domain and provided valuable inputs for the autonomous system development, for example, preserve sensor's last commanded stare-point even once an engage play is ended to allow for Battle Damage Assessment (BDA).

Reference 1 compares a human-autonomy team to a pair of scissors, with one blade representing the human and the other blade representing the autonomy. Regardless of the sharpness of the blades, that is, the respective abilities of the human and autonomy, the scissors' effectiveness is dependent upon the hinge or interface between them. With respect to the current research, the CWA not only helped to sharpen the blade but also polished the hinge, which is indicative of refinements to TECUMSA's autonomy capabilities and HAI.

VIII. CONCLUSION

While this initial CWA was greatly informative, it will not suffice to end analysis at this point. Air assaults are very complex work domains with many prioritization hierarchies, decision makers, scenarios, resources, and so forth. There are still a range of topics that have yet to be thoroughly investigated, including documents used in flight, for example, air movement table, route cards, Excheck, and kneeboard packets, and the range of technology and software being utilized inside of an air assault aircraft, for example, Blue Force Tracker. These additional topics will be addressed with AMC SMEs in follow-up discussions. Additionally, a spiral development method will be used in which AMC SMEs are brought in throughout the development process to test and evaluate TECUMSA as new features are added. Including SMEs throughout the design process will ensure that TECUMSA will be able to effectively support AMCs during current and future air assault MUM-T missions.

14. ABSTRACT
The 2017 ambush of four US special operations soldiers in Niger prompted United States Special Operations Command (USSOCOM) to undertake an "armed overwatch" program to provide a dedicated aircraft to support special operations forces (SOF) across austere environments. Despite Department of Defense (DoD) support, Congress prohibited funding a new aircraft in the 2021 National Defense Authorization Act (NDAA) and mandated more analysis regarding armed overwatch roles and responsibilities, doctrinal changes, and relevance to the future threat environment. Armed overwatch is not a doctrinally defined term. USSOCOM has suggested four existing doctrinal characteristics represent its cumulative character: close air support (CAS), armed intelligence surveillance and reconnaissance (ISR), precision strike, and strike coordination and reconnaissance (SCAR). Instead of clarity, however, the fusion of these doctrinal missions creates friction. This is paradoxical for a glaring reason; the essence of armed overwatch, protecting ground troops from the air, is not a new military phenomenon. Historically, the concept of armed overwatch has deep roots in US military aviation, especially among congressionally mandated special operations activities such as special reconnaissance (SR), direct action, and counterinsurgency (COIN). Mindful of the past, armed overwatch must determine whether to acknowledge challenges of the future threat environment. An era of great power competition viewed through the lens of grey zone warfare provides an analytical approach for armed overwatch below the threshold of large-scale combat operations. Alternatively, the rapid emergence of technological trends characterizes an evolution in warfare that armed overwatch must consider both doctrinally and materially to remain relevant in non-contested environments. The term armed overwatch is presently used interchangeably in various contexts: a program, an aircraft, and a mission. Because of a lack of shared understanding, armed overwatch suffers from a lack of identity and narrative, especially amidst the current and future international security environment. This monograph seeks to apply the lenses of doctrine, history, and the future operating environment to make sense of and "rethink" armed overwatch.

Acknowledgments

I am very thankful to Dr. John Curatola for his direction, insights, and feedback throughout this process. Many thanks are also in order to COL Jason Alvis for his review and suggestions. All errors and inaccuracies in this monograph are mine alone. I am also indebted to many individuals for their valuable insights, feedback, and editing suggestions: Dr. David “El Cid” Neuenswander, George “Skidder” DeFore, Col Aaron “Scratch” Clark, Lt Col Eric “Lomo” Bennett, Lt Col Chris Ibsen, Lt Col Dave “Sugar” Lyle, Lt Col Nathan “Booster” Owen, Lt Col Chad “Sparky” Anthony, Lt Col Dave Erpelding, Lt Col Colin LaFavor, Maj Matthew Barry, Maj John “U-Haul” Fitzsimmons, Maj Bradley Henicke, Maj Nick “KuSS” Narbutovskih, Maj Chris Protos, my classmates in the “B-Team” as well as the Technology and Doctrine Study Group. I am grateful to my children Bella and Evan for the many hours I spent away from family time while locked away in the basement “dungeon.” Thank you to my wife, Angela, the actual planner in our family. This monograph would not have been possible without your love, understanding, patience, and support. I could never be so lucky again. Finally, I am ever mindful of the heroic actions and the ultimate price paid by the four US soldiers that gave their lives in Tongo Tongo, Niger. Staff Sergeant Bryan Black, Staff Sergeant Jeremiah Johnson, Sergeant La David Johnson, and Staff Sergeant Dustin Wright forever have my gratitude and respect. Until Valhalla.

Abstract

Rethinking Special Operations Armed Overwatch, by Maj Matthew J. Sabatino, US Air Force, 68 pages.

The 2017 ambush of four US special operations soldiers in Niger prompted United States Special Operations Command (USSOCOM) to undertake an “armed overwatch” program to provide a dedicated aircraft to support special operations forces (SOF) across austere environments. Despite Department of Defense (DoD) support, Congress prohibited funding a new aircraft in the 2021 National Defense Authorization Act (NDAA) and mandated more analysis regarding armed overwatch roles and responsibilities, doctrinal changes, and relevance to the future threat environment.

Armed overwatch is not a doctrinally defined term. USSOCOM has suggested four existing doctrinal characteristics represent its cumulative character: close air support (CAS), armed intelligence surveillance and reconnaissance (ISR), precision strike, and strike coordination and reconnaissance (SCAR). Instead of clarity, however, the fusion of these doctrinal missions creates friction. This is paradoxical for a glaring reason; the essence of armed overwatch, protecting ground troops from the air, is not a new military phenomenon. Historically, the concept of armed overwatch has deep roots in US military aviation, especially among congressionally mandated special operations activities such as special reconnaissance (SR), direct action, and counterinsurgency (COIN). Mindful of the past, armed overwatch must determine whether to acknowledge challenges of the future threat environment. An era of great power competition viewed through the lens of grey zone warfare provides an analytical approach for armed overwatch below the threshold of large-scale combat operations. Alternatively, the rapid emergence of technological trends characterizes an evolution in warfare that armed overwatch must consider both doctrinally and materially to remain relevant in non-contested environments.

The term armed overwatch is presently used interchangeably in various contexts: a program, an aircraft, and a mission. Because of a lack of shared understanding, armed overwatch suffers from a lack of identity and narrative, especially amidst the current and future international security environment. This monograph seeks to apply the lenses of doctrine, history, and the future operating environment to make sense of and “rethink” armed overwatch.

Introduction and Armed Overwatch Fundamentals

> Airplanes engaged in reconnaissance missions will be prepared to attack hostile ground forces, in order that emergency combat support may be rendered [to] friendly ground units without delay.
>
> —United States Marine Corps, *Small Wars Manual, 1940*

Background

On October 4, 2017, armed Islamic State militants ambushed a United States Special Forces (SF) team near Tongo Tongo, Niger.[1] Four American SF and five allied Nigerien troops died during the attack.[2] The incident represented the most significant combat loss of American lives in Africa since the Battle of Mogadishu in 1993.[3] Subsequent concern over US special operations military activities in Africa led to formal congressional and United States Africa Command (AFRICOM) investigations.

The roles of airborne intelligence, surveillance, and reconnaissance (ISR), command and control (C2), and close air support (CAS) were significant factors in the review of the Tongo Tongo incident. First, an airborne ISR asset that initially supported the SF team during their mission was re-tasked to support another military objective before the team returned to their base.[4] After friendly troops encountered enemy fire, it took ninety-one minutes for a US aircraft to arrive overhead.[5] Second, the area of operations in Africa is geographically large and diverse (Appendix A), and it is impossible to dedicate aircraft to every mission or priority concurrently.

2040 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The AFRICOM investigation found that ISR "was hindered by limited operational planning and procedures, and a lack of coordination and synchronization with US forces and partner nations."[6] The SF team did not receive dedicated airborne ISR throughout the entirety of the mission.[7] Conceivably, uninterrupted ISR coverage, especially from the same platform, would have alerted friendly forces to the advance of potentially hostile forces during critical stages of the mission. Finally, the inability to provide immediate CAS from a US military aircraft was significant. The only available CAS, two allied French fighter jets, were not airborne when the enemy first attacked the SF team.[8] Once the jets arrived overhead to assist, they could not establish contact with the SF team, identify their exact location, or distinguish enemy personnel.[9] Outside of providing a show of force, they were combat ineffective for their intended purpose of providing CAS.

These findings point to a resounding conclusion: an airborne platform capable of providing a distinctive arrangement of dedicated ISR, discrete CAS, and C2 would likely have alerted the SF team to hostile forces and prevented the event's tragic outcome. Today, the Tongo Tongo incident represents a watershed event within United States Special Operations Command (USSOCOM). The outcome serves as a seminal foundation for the acquisition effort of an entirely new USSOCOM aviation program called "armed overwatch."

The armed overwatch program received formal support from stakeholders within USSOCOM.[10] Moreover, numerous opinion articles were published in the wake of the Tongo Tongo incident and argued that a special operations armed overwatch aircraft for USSOCOM is valid and justified.[11] However, congressional concerns about the requirement's validity have jeopardized funding and the program's future. In both houses of Congress, US lawmakers raised questions in committee meetings regarding armed overwatch's overall value, rapid acquisition timeline, operation, sustainment costs, and potential negative impacts.[12] In particular, the Senate Armed Services Committee stipulated "an analysis to define the special operations-peculiar requirements for armed overwatch aircraft and determine whether the acquisition of a new special operations-peculiar platform is the most effective means of fulfilling such requirements."[13] Ultimately, a final bipartisan congressional committee expressly mandated more analysis regarding armed overwatch roles and responsibilities, doctrinal impacts, threats from the future operating environment, and potential materiel solutions.[14] The final passage of the National Defense Authorization Act (NDAA) in January 2021 restricted any funding until armed overwatch could be reviewed, validated, and certified.[15]

Purpose

This monograph analyzes armed overwatch by examining its identity as charged by the 2021 NDAA. The questions below provide a structure for underwriting this primary research task:

1. What is armed overwatch, and what are its doctrinal roles and characteristics?
2. What does a dual framework of special operations unique missions and historical applications of armed overwatch suggest regarding its validity?
3. What is armed overwatch's role and responsibility in future threat environments amid an era of great power competition, and does this indicate a need to rethink alternatives?

Scope

Organizational theorist Karl Weick defines "sensemaking" as the process of "turning circumstances into a situation that is comprehended explicitly in words that serve as a springboard into action."[16] Tongo Tongo's circumstances give meaning to armed overwatch and help give the requirement an identity and a shared narrative. However, as Congress has indicated in the NDAA, more analysis is needed to answer the question of "what is the story of armed overwatch?"

Making sense of armed overwatch requires an understanding of clear roles, responsibilities, and characteristics. The first section of this monograph will examine armed overwatch through doctrine to determine its identity. The term armed overwatch is presently used interchangeably as a program, mission, and potential future aircraft. Armed overwatch's lack of exact meaning prevents common understanding and obstructs identity and narrative development crucial to gaining Congressional approval and funding. Doctrine is a helpful framework to

[16] Karl E. Weick and Kathleen M. Sutcliffe, "Organizing and the Process of Sensemaking," *Organization Science* 16, no. 4 (August 2005): 409.

2043 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

develop a clear and shared understanding of armed overwatch and is valuable in determining a succinct identity and forming a crisp narrative.

Second, special operations activities as defined by US Title 10 law, coupled with historical case studies, provide another lens to analyze armed overwatch. Special reconnaissance (SR), direct action, and counter insurgency (COIN) represent three special operations activities that prove armed overwatch is valid because it is a historical aerial mission. Surprising examples from the American Civil War, early 20th century Marine Corps' expeditions, and Korean and Vietnam Wars illustrate a critical point: armed overwatch is not a new idea or unique to special operations but rather an enduring military phenomenon.

Finally, the character of warfare has changed substantially in recent years due to the shifting geopolitical environment. Armed overwatch must have a clearly defined role in the present era of great power competition. Despite the strategic focus and anticipation of potential major combat operations with Russia or China, conflict below the threshold of large-scale combat in non-permissive environments is likely to persist as a national security threat. A Cold War-era theory of warfare illustrates validity for a "low-end" armed overwatch requirement within a paradigm of peer or near-peer competition. Alternatively, in an entirely different scenario, armed overwatch must be mindful of the future threat environment, especially the semi or non-permissive one. To that end, a manned, fixed-wing armed overwatch platform tied to airfields and dependent on centralized logistics might be doctrinally and materially incompatible with a contested future battlespace.

USSOCOM is unique compared to the military services. It has prescribed express authority by Title 10 US law to pursue the "development and acquisition of special operations-peculiar" equipment and does so through either rapid or deliberate processes.[17] This monograph

2044 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

does not seek to analyze armed overwatch procurement through the lens of the acquisition process. Nor does it "cherry-pick" past or current publications that aim to confirm or deny armed overwatch's validity. Finally, it does not seek to analyze the acquisition program from a financial perspective. The goal, instead, is to separate the "signal" of armed overwatch from the "noise" via an exploration of doctrine, historical revelations, and the future threat environment to discover prescriptive insights and "rethink" the identity of armed overwatch.

Doctrinal Foundations

> AO [armed overwatch] is a non-doctrinal, new term to describe the conduct of Close-Air Support (CAS), Armed Intelligence, Surveillance, and Reconnaissance, Strike Coordination & Reconnaissance, and Precision Strike in direct support of small, geographically isolated SOF units.
>
> —Vice Admiral Tim Szymanski, Deputy Commander, USSOCOM

Armed Overwatch

Doctrine offers fundamental principles for how our military employs its forces through coordinated action toward a common objective.[18] While directive in nature, it is not prescriptive yet provides a logical starting point for military capabilities and troops in warfare. Doctrine can help focus our awareness on what is essential because it is rooted in past lessons. Chairman of the Joint Chiefs of Staff Instruction 5705.01G, *Standardization of Military and Associated Terminology*, mandates military terminology standardization to improve communication and mutual understanding within the Department of Defense (DoD) federal agencies.[19]

2045 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

According to the *DoD Dictionary of Military and Associated Terms*, armed overwatch is not a formally recognized doctrinal term.[20] Occasional armed overwatch references appear across joint and service-wide doctrine publications, but their usage is inconsistent and does not suggest an overall integrated idea.

An acquisition effort for a novel and potentially costly aircraft program without a joint doctrinal foundation requires a greater degree of explanation because it lacks shared understanding. A lack of doctrinal standardization leaves enormous room for interpretation across the joint force, notwithstanding limitations, integration, tactics, techniques, and procedures. USSOCOM acknowledges armed overwatch's mission void and submits that it is the unique combination of the missions of CAS, armed ISR, precision strike, and strike coordination and reconnaissance (SCAR).[21] However, instead of providing clarity, an analysis of these subordinate characteristics generates further misunderstanding through the friction caused by their forced composition. Rather than the emergence of synchronized, "X-centered" doctrine, the result is haphazard stitching together of like doctrines, the equivalent of "Franken-doctrine."

Current US military doctrine provides a minimal reference to armed overwatch. A 2008 military journal article written by current Air Force Deputy Chief of Staff for Strategy, Integration, and Requirements, Lieutenant General Clinton "Q" Hinote, defines armed overwatch as "not CAS, but not ISR either."[22] Joint Publication (JP) 3-05, *Special Operations*, revised and updated in September 2020, makes zero references to the term.[23] The multi-service manual for

2046 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the joint application of firepower, more commonly known as JFIRE, contains no armed overwatch definition.[24]

Because the term armed overwatch lacks definition, we must assign it meaning. Doctrinal gaps and voids offer virtually no foundation for understanding its character and nature and do little to determine its roles and responsibilities of a mission or suggest the program's validity and pursuit of a new aircraft. Therefore, one way of better understanding armed overwatch's identity is through an indirect analysis of its four proposed doctrinal mission characteristics.

Close Air Support

One common criticism of armed overwatch is that it is merely the mission of CAS by another name. The DoD Dictionary defines CAS as "Air action by aircraft against hostile targets that are in close proximity to friendly forces and that require detailed integration of each air mission with the fire and movement of those forces."[25] Likewise, joint doctrine defines CAS as the employment of "speed, range, maneuverability to attack targets that other supporting arms might not be able to engage due to limitations such as target type, range, terrain, or ground scheme of maneuver."[26] These definitions affirm the essence of what a special operations armed overwatch aircraft accomplish: air support to troops on the ground.

Current CAS doctrine does not differentiate between CAS and armed overwatch. JP 3-09.3, *Close Air Support*, references armed overwatch one time in the context of target marking.[27] Similarly, JP 3-30, *Joint Air Operations*, mentions armed overwatch one time regarding tasking

2047 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

of unmanned aerial systems.[28] Creating even more confusion, Air Force Doctrine Annex 3-03, *Counterland Operations*, defines armed overwatch as a "non-doctrinal" mission category within COIN to provide ground commanders full-motion video, situational awareness, and immediate CAS when necessary.[29] Annex 3-03 further elaborates that if a CAS situation does develop, then the armed overwatch mission should be considered CAS and "not a new or independent counter land mission area distinct from CAS."[30] This is the sense of many subject matter experts. According to Dr. David Neuenswander, Director of Army and Air Force Doctrine Integration (and former A-10 pilot): "If I am armed and in a position to support ground troops, this is close air support."[31] The relationship between CAS and armed overwatch and whether they are distinct is a critical question. The Air Force's A-10 Thunderbolt II, better known as the "Warthog," and the historical challenge of C2 of military aircraft provide a framework for analyzing this question more in-depth.

The A-10 was explicitly designed for CAS. In 2018, the A-10 fleet size was deemed inadequate to support the National Defense Strategy's (NDS) requirements.[32] The Department of the Air Force projected 249 A-10 in service in 2021 across the active-duty Air Force, Air National Guard, and Air Force Reserve.[33] However, the A-10 is plagued by the dilemma of age. Even with modern upgrades, the A-10 is nearly fifty years old, and in that span, the total fleet size has slowly eroded. Due in part to this challenge, the Air Force's OA-X Light Attack Aircraft

(LAA) initiative was intended to remedy this readiness imbalance by acquiring a new two-seat turboprop airplane designed for CAS operations in COIN operating environments. Since then, the LAA program has stagnated due to fiscal constraints, manpower limitations, and a national strategy shift toward great power competition. LAA and armed overwatch are mutually exclusive, and both programs will likely not be simultaneously funded. Today, the Air Force's LAA indecision is one reason that has given Congress pause for USSOCOM's separate but similar program. The 2021 NDAA explicitly prohibited the purchase of armed overwatch aircraft until the "Chief of Staff of the Air Force certifies the Air Force does not have the skill or capacity to provide CAS and armed overwatch at present."[34] This delay is necessary for the Air Force to analyze the OA-X program's state and explain to Congress why its current CAS aircraft inventory (A-10, AC-130, MQ-9, F-16, B-1, B-52, and F-15E) cannot meet the present USSOCOM CAS demands.

This illustrates a fundamental and historical C2 problem with CAS. The Air Force tenet of "centralized control, decentralized execution" is predicated on the philosophy that resource-scarce aircraft offer potentially operational and strategic effects.[35] In North Africa during World War II, Army Air Force fighter aircraft were placed directly into Army Corps echelons, and theater-level effectiveness was sacrificed for local effectiveness. Before long, it was realized that tactical airpower characteristics such as speed, flexibility, and range were more effective when centrally controlled at higher echelons.[36] The Air Force C2 model for airpower, allocated under a

single Airmen's authority based on the highest priorities rather than parceled out to subordinate echelons, continues to this day.[37]

JP 3-09.3 states CAS is planned and executed to support tactical ground units at a time and place where friendly forces are close to enemy forces.[38] Additionally, Air Force CAS doctrine considers both preplanned and immediate requests for CAS to allow greater flexibility in planning and Air Tasking Order execution.[39] Air Force doctrine also accounts for "on-call CAS," which "involves putting the aircraft on ground-based or airborne alert during a preplanned time period when the need for CAS is likely, but not guaranteed."[40] The Air Tasking Order can organize CAS as either GCAS (ground alert) or XCAS (airborne alert).[41] Two additional doctrinal methods subdivide On-Call CAS even further. 'Push-CAS' and 'Pull CAS' allow for even greater flexibility to accomplish planned and un-forecasted needs for CAS.[42] These types of requests, missions, and methods advance a shared CAS understanding through doctrine. However, this CAS doctrinal terminology does not comprehensively account for the entirety of an armed overwatch requirement.

An important finding from the AFRICOM Tongo Tongo investigation found that aircraft response time was hindered by "limited operational planning and procedures, and a lack of coordination and synchronization with US forces and partner nations."[43] This finding signals the heart of USSOCOM's request for CAS from an armed overwatch platform: the ability to assign perpetually dedicated CAS independent of centralized C2. XCAS, as a centrally controlled

2050 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

function, cannot assure complete and comprehensive CAS coverage for special operations forces (SOF). Furthermore, XCAS and GCAS cannot guarantee direct support for SOF missions. Therefore, armed overwatch requires a distinctive type of dedicated CAS that is not wholly defined or articulated by the present Air Force CAS C2 doctrine and missions (Appendix C). In particular, the Air Force's CAS integration model is theoretically too centralized and not flexible enough to support SF teams like those operated in Niger. Geographically isolated SOF requires organic and dedicated CAS that provides direct support due to the unique geographical demand of operating in austere environments.

Present CAS doctrine is relatively incompatible with one of the chief requirements of armed overwatch: "direct support of small, geographically isolated SOF units."[44] If one imagines Air Force CAS doctrine and the various requests, missions, and methods as a Venn diagram, then armed overwatch is analogous to the center of this diagram in which present CAS doctrine converges, but no cumulative or independent criteria exist (see Appendix C and Appendix D). Alternatively, resourcing limitations will always persist due to the unique operational environments of SOF. The unique CAS requirement of tactical SOF echelons in the austere environments among unique SOF resourcing requirements illustrates two essential ideas. First, armed overwatch needs to be understood as a mission before a program. Second, a requirement for this type of mission can be filled by CAS capable aircraft but is limited by current CAS inventory, such as the A-10.

Armed Intelligence Surveillance and Reconnaissance

Armed Intelligence, Surveillance, and Reconnaissance also lacks a common joint doctrinal definition. JP 2-01, *Joint and National Intelligence Support to Military Operations*, defines ISR as:

[44] USSOCOM, *U.S. Special Operations Validation of Special Operations Rapid Requirements Document for Special Operations Forces Armed Overwatch*, 1.

2051 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

> 1. An integrated operations and intelligence activity that synchronizes and integrates the planning and operation of sensors, assets, and processing, exploitation, and dissemination systems in direct support of current and future operations. 2. The organizations or assets conducting such activities.[45]

CAS and ISR's relationship is critical to understanding armed overwatch because they represent its two primary missions. Joint doctrine addresses the overlap of the two to a limited degree. JP 3-09.3 lists ISR as a consideration in troop support but not a primary role for CAS.[46] Likewise, CAS and strike platforms are doctrinally defined as "non-traditional" ISR assets that can provide ISR through capabilities such as ground-moving-target indicator tracker or full-motion video sensor data."[47] These sensors, however, are generally "limited in the field of view resolution, or scope of operations when compared to traditional [ISR] sources."[48] In their conduct of ISR, however, they "should only be considered on "an as-needed basis."[49] The doctrinal missions of CAS and ISR do not fully account for one another. Each mission can have varying degrees of the other capability, but a mission representing a fusion of the two doctrines does not presently exist. One could reason the fusion of CAS and ISR creates a void in which CAS and ISR do not account for the other's full doctrinal mission potential proves the legitimacy of an armed overwatch mission. The multi-mission MQ-9 *Reaper* unmanned aerial vehicle (UAV) is an example that illustrates this doctrinal overlap between ISR and CAS in a practical application.

The MQ-9 is an armed, multi-mission asset with an intelligence collection mission that can also perform limited CAS.[50] The special operations variants primarily conduct ISR in direct support of current and future SOF operations. To be sure, the MQ-9 does not match the CAS

2052 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

capabilities of the A-10. It lacks armament because it is primarily an ISR mission with robust electro-optical sensors, advanced radio-communications suites, data-link capabilities, and the ability to transmit and deliver secure voice communications full-motion video. A multi-mission platform that combines CAS characteristics with the advanced suite of ISR sensors is a blend of functions that armed overwatch requires overhead the battlefield, and the present doctrine fails to account for entirely.

The A-10 lacks the multiple advanced ISR capabilities that a multi-mission MQ-9 can employ, while the MQ-9 lacks the considerable weapons complement of ordnance, forward-firing cannon, and CAS the A-10 delivers. Army assets, such as the MQ-1C *Gray Eagle*, the RQ-7B *Shadow*, and AH-64 *Apache*, provide varying degrees of organic ISR and CAS to support a ground force commander's objective.[51] However, even in these direct support roles, aircraft, by being a limited resource, face similar C2 challenges at the division and corps echelons as that of the centralized Air Force construct.

C2 issues that operationally limit CAS for USSOCOM under an Air Force system also affect ISR. USSOCOM has a military department's distinctive role, such as the Army or Air Force, and a geographic combatant command, assigned with "unique functions, responsibilities, and authorities" prescribed by US law.[52] ISR is a significant military demand for all combatant commands and exacerbated by the limited number of airborne ISR platforms and missions allocated to accomplish their intelligence-gathering demands. The cumulative requirement for global ISR demand exceeds capability by a wide margin and is a common geographic combatant

2053 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

command challenge. A 2020 congressional committee noted the DoD could only meet 20 percent of worldwide ISR requirements.[53]

Presently, the Air Force utilizes most of its ISR platforms to prosecute national-level objectives and meet mission requirements.[54] These objectives usually are strategically oriented and generally do not prioritize special operations tactical mission requirements or goals. Air Force doctrine states, "timely detailed and global integrated ISR support is vital to special operations."[55] However, it is illogical to assume dedicated ISR allocated under the global ISR management planning process would receive prioritization, allocation, and decentralization under the purview of SOF, as joint doctrine suggests.[56]

A doctrinal gap exists between ISR and CAS that is not accounted for by current joint doctrine. This void justifies a new mission that more fully blends the doctrinal characteristics of both ISR and CAS. The full potential of both missions is not accounted for by doctrine nor a current multi-mission aircraft. This exclusion highlights the need for a new armed overwatch doctrinal mission and, ultimately, the program.

Precision Strike

In a now common theme, precision strike also has no DoD or joint publication definition. However, it is defined in Air Force Annex 3-05, *Special Operations*:

> Precision strike provides the joint force commander and the SOF operator with specialized capabilities to find, fix, track, target, engage, and assess (F2T2EA) targets. F2T2EA can use a single weapon system or a combination of systems to complete the kill chain. Precision strike missions include close air support, air interdiction, and armed reconnaissance. Attributes associated with precision strike include persistence, robust

[53] Select Committee on Armed Services, House, National Defense Authorization Act for Fiscal Year 2021, 116th Cong., 2nd sess., 2020, HR Rep. 116-442, sect. 176, 270.

2054 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

communications, high situational awareness, precise target identification, lethality, and survivability, as required.[57]

US military UAVs' usage to conduct counterterrorism (CT) operations and hunt high-value targets utilizing precision strikes as part of the F2T2EA process had become widely synonymous with the Global War on Terror. Despite the well-publicized effects of precision strike across mainstream media, however, the term remains remarkably ill-defined. The absence within current US doctrine is even starker. The precision strike concept dates to the mid-1980s when Soviet military authors first characterized it as "a new family of highly accurate, precision-guided deliver systems for non-nuclear munitions."[58] Despite nearly forty years of theory, amidst the employment of drone strikes in US CT operations in Iraq and Afghanistan, an approved joint doctrinal definition for precision strike remains remarkably non-existent.

Former Air Force pilot and author Barry Watt provides a rich study of the evolution of precision strike and makes an essential observation of why the diffusion of precision strike doctrine has been relatively slow. Watt suggests that precision strikes, or what he also refers to as "reconnaissance strike," have not achieved a greater diffusion among allies and adversaries due to complexity and other nations' adoption.[59]

Air Force doctrine defines precision strike as capabilities to conduct F2T2EA via missions that include "close air support, air interdiction, and armed reconnaissance."[60] However, the absence of a formal precision strike definition from joint doctrine is puzzling but does not suggest that armed overwatch is an illegitimate requirement. Though poorly defined in joint doctrine, precision strike has a tremendous identity and shared understanding through its

execution and application (not to mention its ubiquity across media like television shows). Absent clear joint doctrine, the Air Force doctrinal definition of a precision strike as a framework to understand precision strike suggests validity and legitimacy for armed overwatch. It is critical, though, that the precision strike doctrinal "knot" be untangled for the nature of armed overwatch to gain greater comprehensive meaning and clear understanding.

Strike Coordination and Reconnaissance (SCAR)

Ironically, the least familiar doctrinal characteristic of armed overwatch offers potentially the best doctrinal prescriptions for armed overwatch. The DoD dictionary defines SCAR as: "A mission flown for the purpose of detecting targets and coordinating or performing attack or reconnaissance on those targets."[61]

SCAR is codified in joint doctrine and governed by a multi-service publication sanctioned by the Army, Marine Corps, Navy, and Air Force.[62] The current SCAR doctrinal manual organizes SCAR by fundamentals, command and control, planning, execution, and incorporates examples of mission planning guides and even explains the relationship to joint doctrine.[63] Additionally, SCAR has numerous doctrinal examples within service-wide doctrine. Air Force Annex 3-03, *Counterland Operations*, establishes pertinent considerations for SCAR regarding C2, delineations from CAS, and authorities. Likewise, Marine Corps Training Pamphlet 3-20D, *Offensive Air Support*, lists similar essential planning considerations.[64] The level of doctrinal fidelity and resolution that SCAR provides is one possible way to codify and articulate armed overwatch. Also, it is noteworthy that there is no dedicated SCAR platform. Like

CAS, it is a mission that numerous aircraft can conduct, rather than a dedicated platform-centric concept.

Summary

The “Franken-doctrine” approach to creating a new doctrinal mission for armed overwatch from four separate doctrinal missions comes up short. An analysis of present doctrine shows that armed overwatch presently lacks identity because a clear and explicit doctrine of its subordinate characteristics does not exist. An attempt to doctrinally isolate armed overwatch and characterize it is confusing because the components that form its whole are either likewise not defined or too similar. Additionally, CAS and ISR do not account for the unique requirements of C2 requirements suggested by armed overwatch. Armed ISR and precision strike are themselves doctrinally ill-defined and, although they have relative levels of shared understanding via their significant application in the previous two decades. However, using them as foundational reasoning for an entirely new doctrinal mission misses the mark. As the least well-known mission, SCAR prescribes the best doctrinal foundation and an independent model for how armed overwatch could be codified within the doctrine.

A doctrinal analysis proves that a new type of armed overwatch mission is both justified and legitimate, lending validity to the program's ambitions. However, there is considerable ambiguity surrounding the meaning of armed overwatch through the lens of doctrine. Meaning cannot be assigned to armed overwatch until it is better defined and develops a better identity through doctrine. Likewise, the arrangement of its four characteristics within one another is opaque. Complete doctrinal clarity is not a precursor to the fielding or justification of a new requirement. However, for armed overwatch to mature from its present ambiguous state, it must be codified in joint doctrine as a mission. Within the framework of present joint doctrine, armed overwatch makes the most sense as a subordinate mission of CAS.

2057 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Doctrine is just one way to form an identity and create a shared understanding. Fortunately, doctrine is relatively easy to create or modify to assign meaning. Historical examples and case studies provide another way to examine armed overwatch to inform its present identity.

Special Operations Core Activities and Historical Examples

> If the enemy is to be struck while he is most vulnerable, he must be attacked immediately by the air patrol, which discovers him.
>
> —United States Marine Corps, *Small Wars Manual,* 1940

USSOCOM's principal function is to prepare SOF to carry out assigned missions established by US law.[65] Title 10 US Code Section 167(k) lists (but does not define) nine special operations activities: direct action (DA), strategic reconnaissance, unconventional warfare, foreign internal defense, civil affairs, military information support operations, CT, humanitarian assistance, theater search and rescue and other activities that may be specified by the President or Secretary of Defense.[66] These missions, or "activities," are listed among DoD directives, joint doctrine and contain historical examples that provide a litmus test to evaluate the legitimacy of armed overwatch.

Unfortunately, these publications all exhibit minor variations of special operations activities. DoD Directive 5100.01, *Functions of the Departments of Defense and Its Major Components,* name twelve special operations activities to include security force assistance, counterproliferation of weapons of mass destruction, COIN, and information operations.[67] Notably, strategic reconnaissance is excluded and replaced by Special Reconnaissance. JP 3-05

comprises the same special operations activities as the DoD directive but adds Hostage Rescue and Recovery.[68] USSOCOM Publication 1, *Special Operations Doctrine,* adds five new missions while removing one.[69] Finally, Air Force and Army doctrine list nearly identical missions with slight differences. Appendix B summarizes the similarities and differences between these publications.

The lack of standardization between the special operations activities across doctrine is concerning and affects armed overwatch. The dissimilarities affect the potential justification and validity of armed overwatch because it is unclear which comprehensive mission-set is authoritative. Lack of clarity, again, breeds a lack of shared understanding. The absence of a unified list of special operations missions creates confusion regarding scale and scope not only for USSOCOM but externally for service department special operations components, such as Air Force Special Operations Command (AFSOC) or United States Army Special Operations Command.

In the absence of doctrinal clarity, history is the most helpful framework to assign an identity to armed overwatch. The special operations activities of SR, CT, and COIN contain relevant examples of armed overwatch in the earliest military aviation applications. Three examples of armed overwatch shape its identity and give it narrative by proving its historical function and a legitimate and valid requirement.

Special Reconnaissance

The DoD dictionary of military terms defines SR as: "Reconnaissance and surveillance actions conducted as a special operation in hostile, denied, or diplomatically and/or politically sensitive environments to collect or verify information of strategic or operational significance,

[68] US Joint Staff, JP 3-05, *Special Operations,* 30.

[69] USSOCOM, USSOCOM Publication 1, *Doctrine For Special Operations,* (MacDill AFB, FL, 2011), 20-27.

employing military capabilities not normally found in conventional forces."[70] JP 3-05 characterizes SR as a domain-agnostic mission and does not differentiate between airborne or ground domains. This is in error. There is a considerable application of airborne and illustrated through many historical examples. The neglected study of military balloons during the Civil War, the discouraging use of the first observation aircraft in the 1916 Mexican expedition, and the Marine Corps Nicaraguan expedition in the late 1920s provide early examples of SR that illustrate the perpetuity of armed overwatch as a historical function of SR.

Airborne SR visually observes or detects information about the enemy. This is just as true today as it was over two hundred years ago when military aviation was first introduced to the US during the American Civil War. Thaddeus S. C. Lowe, an early balloonist, manned a balloon multiple times in 1861 to support Union forces and become the first individual to direct artillery fire via a telegraph from a balloon.[71] The prospect of ballooning became so important during the Civil War that President Abraham Lincoln personally championed its use to General Winfield Scott, then commander in chief of the Union Army.[72] Although the military balloon never provided a decisive military advantage, Confederate rebels attempted to produce similar military balloons to compete with the Union. Most astounding, towards the end of the war, interest in heavier than air "air-machines" intended for observation and even bombing missions gained brief interest as well.[73] Aerial observation during the Civil War, literally the "first" application of US military aviation, was immediately identified as critical to warfighting. Union military balloons operated in sensitive areas apart from conventional forces to collect information concerning Confederate forces in much the same way that an MQ-9 would be tasked to collect ISR in the

Middle East today. The Civil War ended in 1865, suspending further aerial observation innovation, and it would be another fifty years before Congress would enact legislation to create the first official United States aviation section.

Two years after Congress officially commissioned US Army aviation, the 1st Aero Squadron mobilized in Columbus, New Mexico. In 1916, Eight Curtiss JN-3 "Jenny" biplanes supported the US Army expedition under General John J. "Blackjack" Pershing to capture Pancho Villa in Mexico.[74] The JN-3 was developed and associated as an aerial observer to support ground forces. These "Jenny" aircraft were tasked with observation, reconnaissance, scouting, and other duties supporting ground troops, and the pilots and planes would serve as General Pershing's "eyes" to prevent any surprise attack.[75] Although aviation support in the Mexican Punitive Expedition was far from a success, it brought about public awareness that convinced "Congress to authorize over thirteen million dollars for military aviation."[76] The Congress of 100 years ago recognized the supreme importance of the role of aerial reconnaissance and continued to fund it despite its failures and because of the promise it offered. They did so because they recognized the tactical and operational advantages it could provide. The mandate for SOF and armed overwatch today is no different. A special operations aircraft conducting SR in the airborne domain proves armed overwatch is a legitimate and entrenched historical function.

Another early example of specialized airborne reconnaissance and the advent of CAS is Nicaragua's Marine Corps' occupation. In 1927, rebel Augusto Sandino fought against the American-backed government. A small team of Marine aviators was dispatched to fly biplanes in both reconnaissance and combat roles in a semi-permissive environment to support ground

2061 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

forces. The lessons learned from these aerial reconnaissance successes were captured in doctrine via the Marine Corps *Small Wars Manual*. The 1940 edition includes topics surprisingly relevant to armed overwatch, including: "general considerations, strategic reconnaissance, tactical (close) reconnaissance, infantry missions, and special combat missions."[77] Incredibly, this manual, dated eighty-years ago, states many appropriate prescriptions for armed overwatch today, such as: "it must be remembered that the primary mission of reconnaissance airplanes is not combat, but the procurement of information and the mere existence of offensive armament should not encourage their needless division to combat tasks."[78]

Reconnaissance is not just implied in the definition of SR; it is part of its name. JP 3-05 makes no distinction between ground-based or airborne SR, only mentioning that ISR is not confused with SR.[79] An *Air and Space Power Journal* essay acknowledges this inconsistency and submits that SR requires a formal distinction between air and ground domains.[80] It defines Aerial Special Reconnaissance, or ASR, as a separate and distinct function of SR conducted to fix the threat, visualize the terrain, and anticipate the enemy via functions that ground-based strategic reconnaissance cannot conduct.[81]

The separation of SR into air and ground domains lends additional justification to armed overwatch by giving it meaning through doctrine and a narrative. SOF are accustomed to operating in the deep battlefield as part of an Irregular Warfare (IW) campaign in small tactical echelons. Traditionally, they do not function in the same operational environments as

conventional forces, and they employ SR and capabilities differently. The doctrinal definition of SR defines this capability, and early historical examples illustrate this concept.

Direct Action

The DoD dictionary defines direct action as: "Short duration strikes and other small-scale offensive actions conducted as a special operation in hostile, denied, or diplomatically sensitive environments and which employ specialized military capabilities to seize, destroy, capture, exploit, recover, or damage designated targets."[82] CAS is direct action from the air. The Korean War and the airborne Forward Air Controller (FAC(A)) exemplify direct action as a historical function of CAS and ultimately armed overwatch. Although informally executed during World War I and World War II through liaison and observation planes such as the L-5 Sentinel, the concept of FAC(A) gained significant traction during the Korean War due to ground controllers' inability to move far enough forward to control air strikes effectively.

As a result, the technique of "having a slower plane spot a target and call a jet in to attack" was developed and utilized to find enemy targets, control airstrikes, and enhance CAS due to a lack of artillery and direct army ground movement.[83] The propeller-driven T-6 trainer aircraft and their pilots, collectively known as "Mosquitos," made ideal "slow" FAC(A) aircraft. It was simple, durable, could average between five and six hours in the air per day, and its low stall speed enabled it to loiter and provide better observation of the ground.[84] The concept was operationally successful and received numerous accolades and military citations during and after the war. At the end of the Korean War, the Mosquito program was discontinued; however, no effort to formalize the doctrinal lessons learned occurred. At the time, many believed that future wars would utilize airborne controllers flying in high-performance and faster jet aircraft.

2063 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Mosquito operations enabled direct action via CAS from other airborne assets by flying toward the enemy front to search for enemy targets and provide reconnaissance for friendly ground troops. This methodology, not doctrinally defined at the time, has considerable similarities to the present-day application of SCAR, a characteristic of armed overwatch. Thus, the slow FAC(A) aircraft actions embodied modern-day armed overwatch characteristics like CAS and ISR and proved their validity through their historical use. Unfortunately, many of these lessons were forgotten and not incorporated into doctrine. However, the slow-FAC(A) concept and associated armed overwatch mission would be revisited a few years later in the South East Asia theater.

Counterinsurgency

JP 3-24, *Counterinsurgency,* prescribes relevant approaches and considerations to counter an insurgency and discusses aspects for conducting missions. DoD dictionary defines COIN as "comprehensive civilian and military efforts designed to simultaneously defeat and contain insurgency and address its root causes."[85]

JP 3-24 also details aviation contributions to COIN as "CAS, precision strikes, armed overwatch, ISR" as an alternative to conventional aviation that permits freedom of movement for counterinsurgents in haven and rugged terrain.[86] The explicit mention of armed overwatch in COIN doctrine is crucial because it indicates armed overwatch already exists and has meaning and identity within COIN. Furthermore, COIN doctrine lists direct action and SR as the top two special operations activity considerations for its conduct.[87] The explicit mention of CAS, precision strike, ISR, and armed overwatch is striking and suggests a doctrinal synchronization of

armed overwatch together within COIN. The Vietnam War and the OV-10 "Bronco" provide another historical example of armed overwatch and its characteristics in practice.

The OV-10 was conceived by the Marine Corps and developed under a tri-service program and the Air Force and Navy as a twin-turboprop, multipurpose aircraft designed for COIN operations.[88] The OV-10 was extraordinarily versatile and configurable for observation, armed reconnaissance, gunfire spotting, limited ground attack, but most commonly used by the Air Force as a FAC-A.[89] The OV-10 was unique because it combined lessons from previous wars, including the success of CAS from low-performance aircraft during World War II and the maneuverability and observation of FAC(A) aircraft in Korea with new technology light level TV, to provide real-time video imagery. Additionally, it could be configured to carry rockets, missiles, and up to 3,000 pounds of ordnance.[90]

In 1968, six OV-10 were sent to Southeast Asia under the code name Combat Bronco as part of a task force to evaluate the use of a FAC-A.[91] The following year, as part of project Misty Bronco, a decision was made to experiment with the OV-10 in an armed FAC(A) role since its armament of forward-firing weapons and maximum ordnance load of 3,600 pounds made it ideal for providing "limited by highly responsive airstrike capability to support US Army forces requesting immediate close air support."[92] The results of the test were an overwhelming success. The armament of the OV-10 enhanced the FAC(A) with a "limited but highly responsive airstrike capability," and subsequently, all OV-10 FAC aircraft were armed to support "immediate strike

response."[93] One FAC(A) pilot was asked in a 1969 interview to comment on future FAC(A) conflict compared to Southeast Asia. His response is illuminating: "I would say you would need an OV-10 type airplane, not necessarily the OV-10, but OV-10 characteristics: speed, range, ejection seat, and long-range visibility. Again, I think it should be a simple machine. Not the OV-10 exactly, but with the same characteristics."[94]

The success of the OV-10 and the resemblance of its characteristics with an armed overwatch mission extended beyond Vietnam. In 2012, DoD allocated $20 million toward the partial reactivation of the OV-10. In 2015, two planes deployed and saw combat missions to prosecute the Islamic State.[95] While the latest experiment mainly was a limited proof of concept, it illustrated a suitable alternative to the much more expensive to buy and maintain high-performance jets, which also frees other dedicated assets to train and prosecute peer or near-peer adversaries and targets.[96] Notably, the USSOCOM requirement for armed overwatch has prompted multiple defense contractors to team together to introduce a new variant of the OV-10 Bronco, the "Bronco II," to conduct "ISR, SCAR, CAS, FAC(A) and armed overwatch."[97] This prototype offers a promising next-generation materiel solution built on the successes of its predecessor in Vietnam.

Summary

From the military balloons of the Civil War through the Marine Corps expedition to Nicaragua to the slow FAC(A) in Korea and Vietnam, a persistent theme is clear: armed

overwatch characteristics were exhibited at various times in special operations unique settings in support of the special operation's unique activities. The justification of a new armed overwatch requirement to Congress nests within a historical mission has existed since Lincoln's presidency. Further, this galvanizes a vital point: the "means" that conduct armed overwatch (the aircraft) are a function of the mission.

Armed overwatch case studies from the Civil War, early and mid-twentieth century represent epochs that are not traditionally associated with SOF. However, the functions of ISR, CAS, and C2 from these periods prove that armed overwatch is equally suited for SOF today as it was in the past. ISR, CAS, and C2 may not have been doctrinal terms in the 1860s, but their character emerged, became realized, and their operational importance prized. A 150-year-old military balloon is wholly incapable of conducting armed overwatch over today's battlefield. Similarly, manned, fixed-wing aircraft employed in Korea, Vietnam, Iraq, and Afghanistan might be incompatible with the armed overwatch demands of future warfare. However, these case studies provide a fundamental and historical identity for armed overwatch as a mission.

A broad historical survey of armed overwatch in military aviation illustrates a rich tapestry of forgotten employment lessons, C2, and missions for an armed overwatch concept currently being re-imagined. The past offers numerous examples of concepts and aircraft to justify special operations armed overwatch and its characteristics that recall historical precedent and prove validity. In contrast to the past, however, a look into the future carries its own unique set of trends and challenges to analyze armed overwatch further.

Future Threat Environment

> Victory smiles upon those who anticipate the change in the character of war, not upon those who wait to adapt themselves after the changes occur.
>
> —Giulio Douhet, *The Command of the Air*

Making sense of armed overwatch's identity involves rethinking and anticipating its role and responsibility in the future. The 2021 NDAA specified armed overwatch must analyze "the

2067 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

future threat environment and impacts to concept survivability."[98] Armed overwatch's role in the future operating environment poses an important question, especially amidst warfare's changing character in an era of great power competition. US strategic guidance, a theory of grey zone warfare, a DOTmLPF-P doctrinal concept, and materiel solution alternatives provide a cumulative framework to make sense of armed overwatch's role and responsibility in the future threat environment.[99]

Roles and Responsibility

According to the 2017 National Security Strategy (NSS), US foreign policy has shifted its focus to compete with Russia and China.[100] For special operations, this change represented an abrupt departure from the paradigm of IW and countering violent extremist organizations (CVEO) since 9/11. Missions like CT, COIN, and foreign internal defense, where US forces-controlled tempo and timing across, especially in the air, were suddenly no longer the priority.[101]

The NDS's Irregular Warfare Annex acknowledged this transition and stated the new strategic priority of great power competition while noting that CVEO remains a persistent threat.[102] Most importantly, it established an inextricable link between unified action and IW that

2068 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

connects conventional forces and SOF:[103] This is paramount because it mandates the joint force must institutionalize IW.[104] It also demonstrates a basic logic for SOF and armed overwatch: IW and great power competition are not mutually exclusive but mutually supporting.[105] A Cold-War era theory of warfare from the 1950s provides a structure to understand this logic further and creates a foundation for armed overwatch roles and responsibilities amidst a national strategy of great power competition.

Thomas Finletter, a former Secretary of the Air Force and North Atlantic Treaty Organization (NATO) ambassador, originally described what is referred to as "grey zone" in 1954 as "countries outside of NATO or nearly so with Russia and China."[106] Since then, grey zone warfare has re-emerged as relevant in the contemporary international environment. A 2019 RAND Corporation report stated the United States should expect competition with Russia and China to be "played out primarily below the threshold of armed conflict . . . in the grey zone between peace and war."[107] Furthermore, the 2021 Interim NSS states: "We will maintain the proficiency of special operations forces to focus on crisis response and priority counterterrorism and unconventional warfare missions. Moreover, we will develop capabilities to compete better and deter grey zone actions."[108] Today, grey zone warfare suggests that although competition with Russia or China *might* occur at or above a threshold of armed conflict, it is far more likely to

exist on the conflict continuum below that of large-scale or major combat operations (Appendix E). According to a bi-partisan House Armed Services Committee report on the future of defense, Russia has used private military corporations in Ukraine, Venezuela, Syria, and Libya.[109] Thus, it is reasonable to conclude future indirect challenges from Russia and China proxy forces in the gray zone, especially in parts of the Middle East, Africa, and South America in which SOF have operated in the past in support of CVEO. This manifestation of grey zone warfare in practice, coupled with the 2021 interim NSS, is critical because it gives SOF a mandate to not depart significantly from its execution and support of special operations activities and creates a foundational role for armed overwatch in an era of great power competition.

Great power competition is not synonymous with large-scale or major combat operations. While they exist on a spectrum, by definition, competition, conflict, and confrontation are distinct. Also, great power competition does not equate to high-end major combat or large-scale combat operations. Therefore, the military conflict continuum requires "low-end" missions that are arguably more likely to occur in the grey zone than towards the higher end of the conflict continuum involving large-scale combat operations. Armed overwatch conceptually supports great power competition precisely because it is not a "high-end" mission conducted as part of large-scale combat operations but rather one that supports the rest of the military competition continuum. This logic provides clarity for armed overwatch in great power competition. However, it accounts for only one potential scenario in the future operating threat environment and does not address the dilemma of a contested or denied environment.

The requirement to gain access and then operate in contested domains with degraded systems is a significant military challenge. Senior DoD officials indicated that military conflict with Russia or China, whether it be direct or indirect, would severely challenge and strain the ISR

[109] House, Committee on Armed Service, *Future of Defense Task Force Report 2020* (Washington DC: Government Publishing Office, 2020), 25, accessed September 24, 2020, https://armedservices.house.gov/2020/9/future-of-defense-task-force-releases-final-report.

2070 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

enterprise in a highly contested environment.[110] Since 9/11, SOF aviation has enjoyed relative freedom of access into and within a permissive operating environment. Armed overwatch cannot assume that future conflicts will have unilateral permissive movement and maneuver in the air. While a requirement for armed overwatch amidst permissive environments may persist, this might not always be the case. Therefore, the permissive maneuver assumption comes at the expense and potential risk of future relevancy in a contested environment.

Across permissive environments such as Africa, armed overwatch underwrites a national strategy of great power competition by accounting for the military conflict continuum below the threshold of major combat operations.[111] Alternatively, the future threat environment is likely to be a "sophisticated, highly contested, A2/AD environment" that will be "won by the side with an information advantage, enabling the ability to outpace, outthink, and outmaneuver adversaries across multiple domains."[112] This question of the contested environment presents two very different future scenarios. Armed overwatch must determine its role in exclusive support of low-end missions in a permissive environment versus an alternative future. This includes potential escalation to a non-permissive or even denied environment amidst Access/Area Denial (A2/AD) threats.

Armed overwatch must overcome the contested environment's dilemma if it is meant to account for joint force integration. An emergent all-domain operations joint warfighting doctrine enhanced by future emerging technologies such as artificial intelligence (AI) and autonomous systems provides a doctrinal approach to nest within.

DOTmLPF-P: Doctrine

The 2018 National Military Strategy highlights the "diffusion, competition, and new threats" of technology as likely future security trends.[113] A2/AD, robotics, drone swarms, AI, lethal autonomous weapons, and hypersonic weapons are just a few examples of emergent US technologies in the so-called present "Era of Accelerated Human Progress."[114] Meanwhile, US strategic competitors have also invested in, adapted, and incorporate new technologies to exploit weaknesses and gain relative advantage or superiority across physical and non-physical domains. These emerging "high-end" technologies are relevant for armed overwatch because they point to an integrated technological approach for the joint force within the DoD's technology culture that armed overwatch cannot ignore and must exist within. It is essential for armed overwatch nest conceptually within this new all-domain joint warfighting concept if it is meant to be relevant amidst the contested environment.

A joint warfighting organizational concept for the US military provides overwatching guidance for how the joint force collectively fights. The idea of a joint warfighting concept is not novel and, coincidentally, has precedent in the air and ground domains. General Donn A. Starry, then commander of US Army Training and Doctrine Command, authored a 1981 essay to promote the concept of "extended battlefield," which led to the Air-Land battle doctrine between the Army and Air Force.[115] With the rise of great power competition against the backdrop of emerging technologies in the cyber and space domains, especially A2/AD, a new joint warfighting concept is now necessary. According to the Vice Chairman of the Joint Chiefs of

Staff", the new joint warfighting concept will utilize future all-domain capabilities to overcome the traditional battlefield lines and integrate “fires from all domains, including space and cyber.”[116] This means future capabilities, such as armed overwatch, will connect ISR sensors and fire capabilities in real-time via a more extensive integrated network and across contested or degraded environments.

Armed overwatch must integrate more fully in this doctrine and its future network-centric battlefield under a new future C2 model if it is meant to operate in a semi or non-permissive environment. Joint All-Domain Command and Control (JADC2) is a conceptual solution to operationally connect C2 “sensors-to-shooters” into a single organizational network that uses a typical data architecture. A JADC2 integrated armed overwatch platform could potentially share ISR sensor data in real-time with not just a ground-based SF unit but also long-range artillery, cyber, or space-based assets. To be sure, current manned and unmanned special operations aircraft, such as the MQ-9, already exhibit a partial degree of this capability at the tactical level in the competition space below the armed conflict threshold. The benefits of JADC2, however, primarily emerge at the operational level of war. The following example illustrates a practical example of potential armed overwatch integration with JADC2 at the operational level of war.

Project Convergence is the Army’s modernization strategy to enable multi-domain operations and integrate into JADC2 by creating simultaneous effects from all domains faster than the enemy.[117] In an integrated multi-domain “close fight” scenario, an MQ-1C “Grey Eagle” could integrate with a multipurpose helicopter within a JADC2 network to simultaneously

2073 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

incorporate low-earth-orbit satellites to find a ground-based target, sense air targets, and communicate with a ground-based artillery system to destroy the objective.

The preceding scenario is not from the distant future; it occurred in September 2020. More astonishing, the entire sequence took twenty seconds.[118] It demonstrated the revolutionary potential of JADC2: autonomy. Semi-autonomous military operations with a "human in the loop" are not optimized for non-permissive threats in which the speed of the decision is critical. "Human-on-the-loop" operations, enabled through JADC2, could potentially leverage a degree of autonomy where rapid observation, orientation, decision, and action deliver much fast and synchronized effects.[119] JADC2 is the means to enable decentralized execution, rather than vice versa.[120] Mission command through decentralized execution is a hallmark of SOF, and armed overwatch within a JADC2 architecture in a future threat environment amid potential degradation supports that idea by enhancing the operational decision.[121]

The future threat environment requires an operational organization that leverages decision speed to create opportunities and presents multiple dilemmas for the enemy. Expanding decision space is a salient theme of all-domain operations and JADC2, and armed overwatch must nest within this operational logic if it is meant to be relevant in a contested environment. Armed overwatch within an all-domain warfighting concept connects SOF, through mission command, to enhance decision. Enhanced operational agility across multiple domains, enabled by armed overwatch, has the potential to create more opportunities and options for SOF commanders

and their teams against the enemy.

The above section made a case for the validity, necessity, and requirement of a legacy-based armed overwatch capability to support SOF amidst the fringes of great power in a permissive or contested environment. Meanwhile, the 20th-century paradigm of a low-end, manned, fixed-wing airplane supporting SOF troops in either environment might be altogether incompatible with future warfare trends and threats. These scenarios present two possible futures for the roles and responsibilities of armed overwatch. Senior military leaders and Congress must determine the final way forward. Alternatively, small, unmanned aircraft systems (sUAS) technology paired with AI autonomy and a recent military conflict in the Lower Caucasus might offer a hybrid of both armed overwatch future scenarios and account for both contested and permissive environments.

DOTmLPF-P: materiel

USSOCOM SOF Truth 1 states: "Humans are more important than hardware."[122] This maxim seems fundamentally at odds with the trend of emerging technology on and above the future battlefield and the operating concepts that aim to deepen battlefield dependence on networked technology under JADC2. For that reason, it must be addressed. In *Army of None*, author Paul Scharre provides a structure for analyzing the paradox of technological means and SOF ethos via different degrees of autonomy.

Scharre states in "human-in-the-loop" autonomy, a machine performs a task before querying a human before taking action.[123] "Human-on-the-loop" empowers a machine with the abilities of sensemaking, decision, and action, with a human supervisor capable of intervening, if

[122] USSOCOM, "SOF Truths," accessed January 30, 2021, https://www.socom.mil/about/SOF-truths.

[123] Scharre, *Army of None*, 29.

2075 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

necessary.[124] Finally, in "human-out-of-the-loop" operations, a machine is given complete autonomy independent of human action.[125] As robotics, machine learning, and AI continue to advance rapidly, armed overwatch must co-evolve within the present and future technological climate to accommodate these trends to be relevant in the future contested threat environment. For the present and foreseeable future, out-of-the-loop autonomy remains morally and ethically murky at best. However, in the case of armed overwatch, a materiel solution must strike a balance between the requirements of the present versus the anticipated trends of the future battlefield. sUAS offers a 21st-century alternative to the 20th-century aircraft paradigm of a manned, fixed-wing, legacy aircraft.

A key finding from a 2019 RAND study on distrusted air operations in a future battlespace was that the current force presentation model is incompatible with the future contested environment.[126] sUAS offer one way to mitigate this risk through an alternative to a manned aircraft. An sUAS armed overwatch capability is not bound by limitations such as austere forward arming and refueling points or airfields like a legacy fixed-wing aircraft.

sUAS provides cost-effective, persistent surveillance and reconnaissance capability for collection deep in enemy territory.[127] sUAS can also be transported organically with an SF team, such as the one that operated in Tongo Tongo with a low profile. This is precisely the location on the battlefield where special operations forces are likely to operate: in-depth. sUAS, unlike a legacy fixed-wing aircraft, does not have to fight its way past A2/AD into a non or semi-permissive environment like a legacy aircraft. Instead, its portability allows it to be transported,

2076 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

configured, and launched by an operator. sUAS can be quickly configured or launched to conduct ISR and a limited degree of CAS or precision strike to alert or protect ground forces.

sUAS is not without its limitations. To be sure, sUAS significantly lacks the full complement of capabilities and effects a larger aircraft could provide, such as offensive armament and loiter time. However, sUAS technology will only continue to develop and accelerate. An SF team equipped with sUAS has a limited range of ISR or CAS. Some sUAS require a significant amount of manpower. For example, an eleven personnel team operates the Army's "Scan Eagle" UAV.[128] Also, as drone technology advances, so does counter-drone technology. Electronic attacks and cyber capabilities are two of the most obvious ways to neutralize drones, rendering their ISR, communication, data, and weapons combat ineffective. Technology to "harden" drones to function against these threats will continue to advance to mitigate these threats, but it is folly to envision every vulnerability can be protected in every instance. The robotics revolution, led by cutting-edge defense organizations such as Defense Advanced Research Project Agency, offers continued promise through technology that enables "swarm tactics" and incorporates varying degrees of coordination and redundancy amongst many lightweight drones.[129]

As previously stated, SOF may not always operate in austere and isolated environments independently of conventional forces as they have in the previous two decades. Chairman of the Joint Chiefs of Staff, GEN Mark Milley, stated: "In the future, I can say with very high degrees of confidence, the American Army is probably going to be fighting in urban areas."[130] One future scenario offers a much different alternative to the operational environments of deserts in Africa or mountains in Afghanistan. A military conflict in the Southern Caucasus provides an unlikely

2077 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

glimpse into one potential future scenario relevant for armed overwatch in which the "old" way of conventional warfare involving armored warfare and artillery was blended with the contemporary use of sUAS.

The use of sUAS in a modern military conflict, in which SOF and conventional forces operate in tandem, offers insights into the future of war that must be considered for an sUAS armed overwatch capability to operate in a non-permissive environment. The six-week conflict in the Southern Caucasus between Armenia and Azerbaijan in 2020 involved small, lightweight, and relatively inexpensive sUAS. Azerbaijan employed an arsenal of Israeli and Turkish drones to destroy "up to 100 Armenian tanks and armored vehicles, 100 artillery pieces, 150 vehicles, and 60 air defense assets."[131] Heavy losses were inflicted upon Armenian armored forces due to Azerbaijan sUAS drones purchased from Israel and Turkey.[132]

Furthermore, Azerbaijan forces employed the lightweight "Orbiter 1K" (Appendix F) as a "kamikaze drone" in which it flew like a cruise missile into a target and self-destructed.[133] In a first in warfare, the drone attack video was circulated almost immediately afterward across social media platforms. "Cheap airpower" drones indicate a future battlefield trend that incorporates airpower and armed overwatch elements that have applications for both conventional and special operations warfare. These applications allude to a potential future where SOF and conventional forces integrate across the future battlefield, an idea nested with IW guidance.

sUAS, such as the lightweight PC-1 multipurpose quadcopter, offers a materiel solution that provides an alternative worthy of analysis for an armed overwatch program. The PC-1 quadcopter (Appendix H), manufactured by Ukraine, is a vertical take-off and landing multi-role

helicopter that can carry a variety of payloads, can be configured for multiple ISR sensors, and can be equipped for a variety of missions such as "ISR, detection, and tracking of ground targets, and search and rescue."[134] It can be set-up in two minutes, can operate up to an altitude of about 3,000 ft. to transmit video and telemetry data up to five kilometers, and fits inside a backpack.[135] The downside of this technology comes with certain limitations and is not perfect. Radio and video communications are susceptible to interference such as jamming and are limited by range and line of sight. Although it can only stay airborne for up to thirty-eight minutes, that time is sure to improve as battery technology improves.

Summary

US national strategy indicates a new approach to the American way of war in an era of great power competition. For armed overwatch, the future threat environment poses challenges such as the contested operating environment. Simultaneously, a new joint warfighting concept driven by emerging technology aims to synergize military services and capabilities across all battlefield domains. Today's grey zone presents many of the same fundamental missions of the previous two decades, accompanied by technology's emergent challenges. In an era of great power competition, all-domain operations, and sUAS alternatives to warfare, armed overwatch cannot exist in a special operations silo and must account for these hybrid operations alongside conventional forces. Drones such as the PC-1 and others' applications in recent warfare suggest trends in the future operational environment such as AI that cannot be ignored. To be sure, the technology has not yet advanced to the point where it can fully meet the operational demands that can presently satisfy the required characteristics of armed overwatch. However, the technological gap is closing, and this will not always be the case. For this reason, armed overwatch must be conscious of the future threat environment and integrate emerging technology.

Findings, Recommendations, and Conclusion

The purpose of this monograph was to apply frameworks of doctrine, history, and the future operating environment to make sense of and "rethink" armed overwatch. Armed overwatch means something different to everyone (doctrine, concept, mission, aircraft, program, tactic) because it lacks shared understanding. Although doctrine cannot (and should not) prohibit the execution of a mission or acquire a new requirement, it is a tool to explain what is likely to work as the best way to accomplish a task.

Armed overwatch is presently a topical subject within both AFSOC, USSOCOM, and Congress. The findings and recommendations are offered as pragmatic recommendations for staff and leaders associated with the armed overwatch program.

Findings and Recommendations

Finding/Recommendation 1 – Armed overwatch is a mission and must be codified into doctrine. Doctrine can formally define the roles and responsibilities of armed overwatch and describe its nuances, especially between CAS and ISR. JP 3-05, *Special Operations* is an ideal doctrinal publication to explain armed overwatch and specify its unique nuances of CAS, C2, ISR, precision strike, and SCAR. Fully accepting armed overwatch as doctrinal is not the primary barrier to validating armed overwatch as a requirement. However, recognizing the voids and nuances between its doctrinal concepts further legitimizes a mission not fully accounted for by present ISR and CAS technology and capabilities.

Finding/Recommendation 2 – Armed overwatch makes the most sense as a subordinate doctrinal mission of CAS. CAS is most effective when equipped with a premier sensing ability. Integration of armed overwatch into a joint doctrine as an independent doctrinal mission is a challenging approach that requires joint-service support and endorsement. The fastest way to get

2080 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

armed overwatch codified into doctrine is via an annex or appendix to the JFIRE.[136] The Air Land Sea Application Center, located at Langley Air Force Base, is "a multi-service (Joint) organization which produces Multi-Service Tactics Techniques and Procedures.[137] Armed overwatch could also be incorporated much faster as a doctrinal "tactic" and explained as a multi-service tactic, technique, procedure.

Finding/Recommendation 3 – The requirement for armed overwatch is primarily a problem of resourcing. Without armed overwatch, SF teams like in Tongo Tongo are at the mercy of democratizing theater resources that could alert, enable, or protect them. CAS and ISR aircraft are limited resources that are centrally controlled, allocated, and apportioned. As such, they are unlikely to be provided in direct support for SF teams. This is evidenced by the absence of a dedicated US CAS asset at Tongo Tongo. Therefore, the identity and narrative for an armed overwatch requirement at its core is a requirement for a dedicated CAS/ISR hybrid capability for USSOCOM.

Finding/Recommendation 4 – Armed overwatch special operations activities. The special operations activities provide a framework within the mandate of US law to justify armed overwatch. As illustrated, armed overwatch supports SR, direct action, and COIN special operations missions. This list, not all-inclusive, justifies armed overwatch as charged by the 2021 NDAA because it demonstrates to Congress that it supports the very law they had previously passed. However, the lack of standardization of the special operations activities across doctrine is a notable concern outside the monograph's scope and warrants additional attention.

Finding/Recommendation 5 – Armed overwatch is unquestionably a historical function of US military aviation. Rather than illustrate examples of armed overwatch in the eras of

[136] Lt Col Nathan L. "Booster" Owens, telephone interview with author, February 16, 2021.

2081 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

USSOCOM and AFSOC, historical examples of armed overwatch that predate these institutions provide richer meaning and prove it is a historical and enduring mission. Indeed, the IW Annex to the current NDS states that "IW is an enduring mission and core competency. It is "a persistent and enduring operational reality employed by non-state actors and increasingly state actors with the United States."[138] Civil War ISR, early 20th century CAS, and Korean and Vietnam War SCAR suggest armed overwatch is a historically entrenched aviation mission, albeit by different names.

Finding/Recommendation 6 – Armed overwatch is a topical issue for Air Force Special Operations Command. According to the AFSOC guidance strategy from 2020, the fielding of a cost-effective multi-role armed overwatch platform is a strategic focus area.[139] One major challenge for AFSOC regarding armed overwatch is to reconcile armed overwatch within a great power competition strategy while also being clear-eyed about present operational demands.

In permissive environments, armed overwatch represents a crucial currency in underwriting great power competition, especially in the gray zone. However, a significant question of identity and roles and responsibilities persists, requiring senior leader and probable congressional discernment. One armed overwatch narrative envisions a future in which armed overwatch exclusively supports SOF across austere and permissive environments as a "low-end" mission. These gray zones represent seams in great power competition that asymmetrically benefit United States strategic interests. This armed overwatch future scenario foresees strategic support of great power competition along the geographical fringes against proxies and in support of missions like CT, COIN, and CVEO. Although China has emerged as the pacing threat for the DoD, the need to compete along the competition continuum below the armed conflict threshold

[138] US Department of Defense, *Summary of the IW Annex to the National Defense Strategy 2020,* 2.

[139] Air Force Special Operations Command, AFSOC Strategic Guidance, May 26, 2020, 9, accessed March 17, 2021, https://media.defense.gov/2020/May/26/2002305551/-1/-1/1/AFSOC%20STRATEGIC%20GUIDANCE.PDF.

2082 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

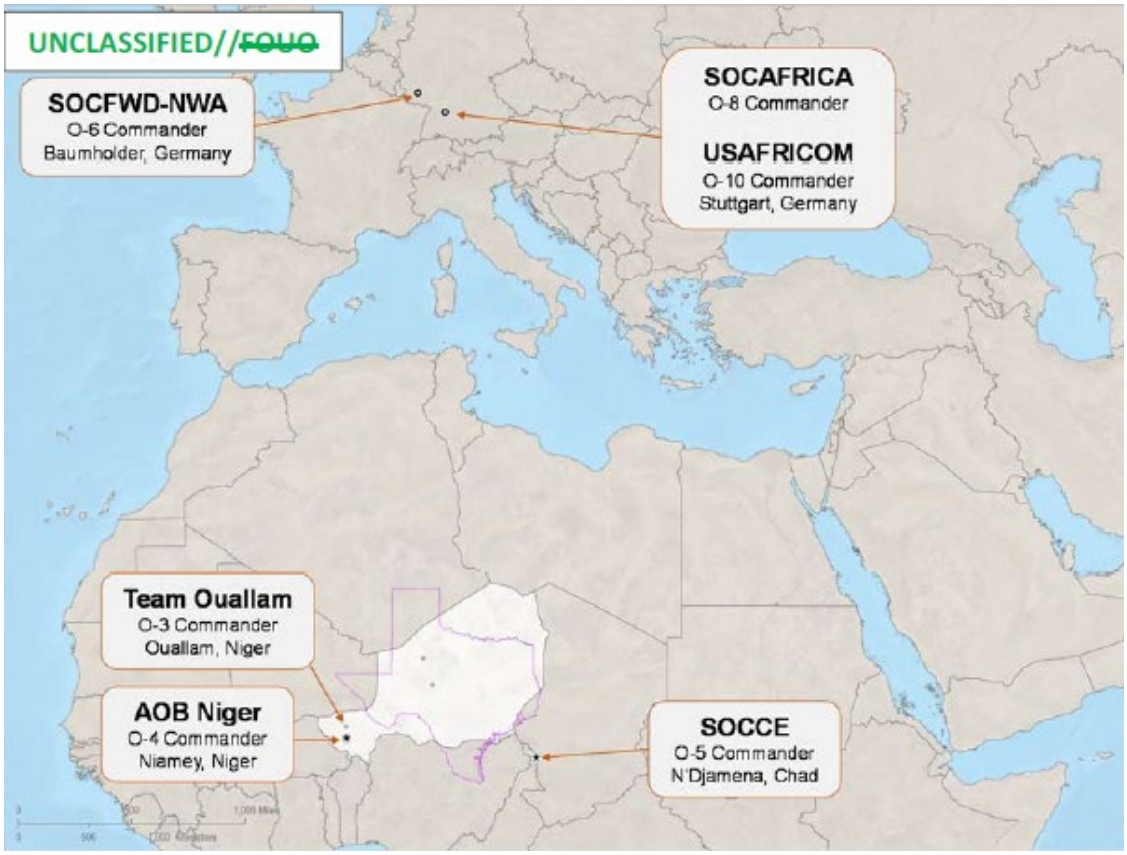
remains necessary and is unlikely to end soon. In this scenario, armed overwatch supports the special operations activities. It underwrites great power competition by fulfilling a persistent requirement across the military conflict continuum to support missions other than major war.

This first scenario assumes that armed overwatch will primarily operate in an austere environment that will always remain generally permissive or uncontested. Alternatively, a second future scenario and an essential question for armed overwatch remain its role, if any, in a contested environment. SOF are likely to play a significant role in Africa or similar environments should competition with China or Russia escalates horizontally or vertically. If great power competition does escalate, Russian and Chinese organic or proxy forces in low-end armed conflict across Africa, Middle East, Asia, and South America may rapidly intensify their involvement resulting in a contested environment and present A2/AD challenges that a low-end armed overwatch capability or asset may be unprepared to adapt within.

Finding/Recommendation 7 – Armed overwatch must consider future warfare characteristics and cannot ignore the challenge of contested environments. sUAS offers the ability to operate in contested airspace or a permissive environment. The use of small, lightweight drones in warfare as recent as the 2020 conflict between Armenia and Azerbaijan indicates a future warfare technological trend that suggests an alternative to present armed overwatch acquisition considerations.

Conclusion: Special Operations Armed Overwatch Re-thought

Armed overwatch has problems related to policy decisions, resourcing, and technology challenges that require senior military leaders and Congressional resolution. Additionally, current trends on and above the battlefield point toward a new age of warfare characterized by irregular adversaries relying on technology-driven capabilities. Without a nearly constant and locally capable armed overwatch capability, today's SOF cannot survive to build access in permissive, semi-permissive, or non-permissive operational footprints. This scenario jeopardizes the US's



2083 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

ability to develop and deepen alliances with partners and gain or sustain access to environments necessary to compete in great power competition.

It is challenging to assign narrative in the absence of shared understanding. Doctrine, history, and the future threat environment lend legitimacy to armed overwatch by rethinking its identity and nuances. A scenario is one way to promote shared understanding and provide a straightforward narrative for armed overwatch. In one respect, this already exists. Tongo Tongo creates a baseline to understand armed overwatch as a mission in which an airborne capability provides dedicated effects of responsive CAS, ISR, precision strike, and SCAR. Likewise, past and present doctrine, the special operations activities, examples from military aviation, and the future threat environment provide prescriptive insights into armed overwatch to rethink its identity, sharpen its narrative and promote a shared understanding.

14. ABSTRACT

Marine Special Operations Command (MARSOC) and its service conventional partner, the Marine Corps, have increased integration, interoperability, and interdependence (I-3) since 2006 when MARSOC was formed. To be better prepared for future threats and challenges in what has been called, "The Age of Everything," MARSOC will be required to build upon MARSOC-Conventional Forces (CF) I-3 and strengthen and build interagency I-3. In order to identify and combat future threats, MARSOC must continue to develop further I-3 between service, joint conventional forces, and its increasing interagency partners. MARSOC-CF I-3 begins with understanding the future threats. MARSOC-USMC I-3 and MARSOC-Interagency I-3 are the fundamental concepts of increase I-3 for MARSOC. To build and increase I-3 between MARSOC, the Marine Corps, and the interagency the future operating environment in which all three players will respond to must first be identified. Once the future operating environment is established, MARSOC can align with the Marine Corps and its interagency partners by better integrating, becoming more interoperable, and interdependent.

Executive Summary

Title: Prevailing in the "Age of Everything": Marine Special Operations Command and Improved Integration, Interoperability, and Interdependence

Author: Major Nathan L. Golike, United States Marine Corps

Thesis: Marine Special Operations Command (MARSOC) and its service conventional partner, the Marine Corps, have increased integration, interoperability, and interdependence (I-3) since 2006 when MARSOC was formed. To be better prepared for future threats and challenges in what has been called, "The Age of Everything," MARSOC will be required to build upon MARSOC-Conventional Forces (CF) I-3 and strengthen and build interagency I-3. In order to identify and combat future threats, MARSOC must continue to develop further I-3 between service, joint conventional forces, and its increasing interagency partners. MARSOC-CF I-3 begins with understanding the future threats. MARSOC-USMC I-3 and MARSOC-Interagency I-3 are the fundamental concepts of increase I-3 for MARSOC.

Discussion: To build and increase I-3 between MARSOC, the Marine Corps, and the interagency the future operating environment in which all three players will respond to must first be identified. Once the future operating environment is established, MARSOC can align with the Marine Corps and its interagency partners by better integrating, becoming more interoperable, and interdependent. MARSOC shares many core tasks with the Marine Corps and has numerous solutions for future I-3. These MARSOC and Marine Corps solutions are represented in: Marine Corps air capabilities (Marine Air integrated with SOF for tailored response operations, utilizing already established fixed and rotary wing assets to conduct SOF training and operations), Marine Air Ground Task Force (MAGTF) and SOF capabilities (MAGTF-SOF Capabilities, Marine Corps assistance to SOF core tasks, MAGTF-SOF digital systems interoperability and operations/intelligence fusion), MARSOC-Marine Corps I-3 in Common Operating Areas (Liaison elements between SOF and USMC, sharing geographic alignment responsibilities), I-3 through Intelligence (Enhanced concept of intelligence, filling the Electronic Warfare (EW) capabilities gap, networking for rapid/precise fires, and USMC and MARSOC theater intelligence, surveillance, and reconnaissance (ISR)) and lastly through training (Urban operations and complex terrain, and expeditionary logistics). MARSOC and its interagency partners can seek to expand I-3 through expanding the global SOF network, increasing liaisons, and through MARSOC's further and expanded commitment to Irregular Warfare.

Conclusion: In order to combat future threats, MARSOC will have to increase its I-3 with CFs and its interagency partners. By examining the future threats and operating environments there are multiple I-3 solutions and themes that assist the Marine Corps, MARSOC and the interagency to better combat future threats. MARSOC will be required to further develop service relationships with the Marine Corps in overlapping area within training, equipping and operationally. Additionally, MARSOC must further develop established interagency

partnerships. The I-3 solutions represent a model to identify, coordinate and implement better I-3 between MARSOC, CFs and the interagency.

Prevailing in the "Age of Everything": Marine Special Operations Command and Improved Integration, Interoperability, and Interdependence

Since the creation of Marine Special Operations Command (MARSOC) in 2006, integration, interoperability, and interdependence (I-3) between the Marine Corps and conventional forces (CF) has improved. To be better prepared for future threats and challenges in what has been called "The Age of Everything," MARSOC will be required to build upon MARSOC-CF I-3 and strengthen interagency I-3. This paper first examines future challenges for MARSOC and a way forward that supports multiple future operating concepts. It will then examine relationships with the greater Marine Corps focusing on manpower, training, and equipping. Finally, it will explore MARSOC-interagency relationship with the aim of enhancing whole of government I-3.

In addition, this paper develops a "concept" for I-3. For the purpose of increased understanding of I-3, the below definitions are critical to understanding the theme of this concept. Integration is the arrangement of military forces and their actions to create a force that operates by engaging as a whole.[1] Interdependence is the purposeful reliance on each other's capabilities to maximize the complementary and reinforcing effects of both.[2] Lastly, interoperability is the ability of both organization's systems, units, and forces to exchange information and services to operate in synergy in the execution of an assigned task.[3] In 2016, the Marine Corps created The *Marine Corps Operating Concept (MOC): How an Expeditionary*

Force Operates in the 21st Century to describe how the Marine Corps will conduct the range of military operations (ROMO) in accordance with its Title 10 responsibilities.

Part 1: MARSOC's Future Operating Environment, The Age of Everything

SOF provides critical capabilities to resolve future crises and support major operations. Success in the future environment will be determined by SOF's ability to navigate conflicts that fall outside traditional peace-or-war constructs. SOF's greatest value to the nation lies in its global perspective, coupled with the ability to act early with partners to provide a range of options for policy makers. Operating ahead of crisis allows SOF and partners to develop long-term and cost-effective options to prevent or mitigate conflict.[4] MARSOC will be required to develop a deeper understanding of the environment to see and act ahead of flashpoints of instability, inform the development of US options, and reduce operational and strategic blind spots.[5] In order to create critical tasks needed to be prepared for the future operating environment, MARSOC must establish a future operating concept that draws upon joint, service and SOF future operating environments. The degree to which MARSOC will contribute to the United States' (US) future defense will depend on its ability to recognize and adapt to the challenges of the future operating environment.[6] The joint operating environment (JOE) focuses on powerful states and non-state actors that establish their own sets of rules against the US and its interests (contested norms). The joint future operating environment also directs the joint force to address a second issue where weak states become increasingly incapable of maintaining domestic order or good governance (persistent disorder).[7]

[7] U.S. Joint Staff. *Joint Operating Environment (JOE) 2035: The Joint Force in a Contested and Disordered World*. Washington, DC. (14 July 2016): 4.

In addition, the Marine Corps' Future Operating Environment (FOE) focuses on the control of information and defending across all domains. Conflict will be fought by ideologically aligned coalitions and their proxies. Armed intervention will be only one tool in an increasingly information-centered battlespace. The US and its allies will play a key role in how to counter the proliferation of old and new weapons of mass destruction (WMD). Information and influence operations will shape the political and social battlespace.[8] The future operating environment will be characterized by an increasingly complex set of challenges in every part of the world. These challenges will range from the destabilizing influence of state aggression, to the expansion of radical networks across regions, to the growing threat of information warfare.[9] Threats will be increasingly transnational, trans-regional, and multi-domain. This era of extraordinary security challenges has been described as "the age of everything," an age where commanders must meet the high demand for all types of missions and threats.[10] Beyond the employment of improved technology, adversaries will continue to blend traditional and irregular techniques, capabilities, and resources to execute hybrid approaches in the gray zone[11], the space between peaceful competition and war.

To respond and prepare for future threats, MARSOC will continue its emphasis on a limited footprint and will find itself as a key constituent to any US response. The first US combat elements to respond to this future threat will be the US SOF and the MAGTF. MARSOC will have to grow in areas to be better equipped to respond to threats. Within all future operating concepts, the use of SOF as a tool will increase. In order to fully understand each problem that MARSOC is faced with and respond correctly without escalating tensions will entail accepting a

certain level of political risk. The complexity of a particular situation will likely require a wide range of interagency and allied partners to understand and an even larger network of capabilities to address.[12] This will require MARSOC to establish better interagency partnership and a better relationship with the Marine Corps.

MARSOC and the Marine Corps mission sets will include assisting in security missions, protecting vulnerable US diplomatic facilities, supporting counterterrorism (CT), and protecting innocents.[13] Marine Special Operation Forces (MARSOF) will execute missions set against the context of regional competition or instability. The complexity of the operating environment will dramatically challenge the ability of leaders at all levels to understand it and come to meaningful solutions. MARSOC formations must be prepared to solve volatile, complex, multi-party, high-stakes problems that defy the application of traditional US strengths and solutions.[14] As conflict moves further into the information and cyber spaces, MARSOF will find itself leveraging theater, interagency, and national level tools to achieve desired outcomes.[15] Globally integrated operations will encourage collaboration across the Joint Force and with partners. These operations allow stakeholders to bring differing perspectives and capabilities to bear on complex challenges.[16]

Part 2: MARSOC-USMC I-3

Several Marine Corps capabilities intersect with special operations (SO) mission sets. By comparing a services' general-purpose forces (GPF) and its SOF component, the Marine Corps

2109 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

and US Army (USA) have the most overlap and ability for I3. All core tasks that MARSOC conducts are comprised of several functions that conventional Marine intelligence, logistics, aviation, infantry, communication, and reconnaissance units can support or conduct. This overlap is seen as many support personnel rotate between conventional and SOF units. SOF missions have resulted in a situation in which MARSOC and the "Big Marine Corps" retain significant overlap in mission competencies.[17] Both MARSOC and the Marine Corps gain from integrating capabilities that ultimately sharpen each other's skills. MARSOC can develop better I-3 in four areas: Marine Corps air capabilities, MAGTF capabilities, geographic common operating areas, intelligence collection, and training.

Marine Corps Air Capabilities within I-3: Marine Air Integrated with SOF for Tailored Crisis Response Operations, USMC HMLA (Marine Light Attack Helicopter Squadron) and MARSOC Relationship in the Conduct of SOF Training and Operations

Marine Air Integrated with SOF for Tailored Crisis Response Operations:

MARSOC and the Marine Corps can build on the relationships and capabilities that the Navy and Naval Special Warfare (NSW) already possess. U.S. Navy assault support helicopter platforms have already established effective relationships with NSW SOF elements. This relationship has established the very best tactics, techniques and procedures (TTP) for specific amphibious and maritime operations such as vessel visit, board, search and seizure (VBSS) operations. MARSOC has worked to better its VBSS TTPs through working with these same U.S. Navy helicopter units. The USMC would gain from working with both NSW and U.S. Navy helicopter units in VBSS operations. By dedicating an Marine light attack helicopter squadron

[17] Schroden, Jonathan, David Broyles, Vera Zakem, Jerry Meyerle, and Ryan Evans. *Improving SOF-GPF Integration for Crisis Response: An Action Plan for HQMC and SOCOM.* Center for Naval Analysis, Arlington, VA. (December 2015): 24.

(HLMA) to both the east and west coast MARSOC elements that train specifically to SOF TTPs, the Marine Corps will gain experience that remains in its own aviation community. The Marine Corps and MARSOC gain by working with each other on these types of mission profiles on a regular basis and get bilateral training on critical mission sets.

MARSOC and the USMC should also explore the use of Marine Corps aircraft to set up VBSS elements. The Marine Corps is not currently equipped to support "bottom up" or boat assault force (BAF) operations. The Marine Corps conducts limited bottom up VBSS operations and requires navy assistance. The Marine Corps is able to support "top down" or helicopter assault force (HAF) VBSS operations through organic MAGTF air support. MARSOC and the USMC should partner to create USMC aerial support element for VBSS operations. The aerial support element would consist of a Marine assault force (Marine Corps reconnaissance element or MARSOC), a rotary wing assault support element, a possible rotary wing escort element, and a fixed wing element to command and control the task force and provide initial sensor support on the target.

USMC HMLA (Marine Light Attack Helicopter Squadron) and MARSOC Relationship: MARSOC is not set to establish its own aviation element in the near future but, can establish relationships with Marine Corps aviation elements that accomplish similar results. In order to better develop a relationship between MARSOC and the Marine Corps, both elements should focus on strengthening each other's strongest capabilities. Assault support, ISR, close air support (CAS), Close Combat Attack (CCA) and an ability to provide overhead command and control, are critical to both MARSOC and the MAGTF, however, both elements do not greatly assist each other in training or during combat operations to the full extent. The Marine Corps and MARSOC would greatly benefit in forming a HAF element that works solely with SOF elements

and trains to specific special operation (SO) missions. This element would not solely be utilized by SOF elements. The HAF element should be comprised of Marine aviation assets both rotary and fixed wing. The concept has functioned inside of Operation Enduring Freedom (OEF) but has since been lost. The concept also worked between the navy and NSW through the Helicopter Sea Combat Squadrons (HSC). Although only a single HSC squadron still exists, HSC-85 is dedicated to special operations support as its primary role and can be tasked by USSOCOM. HSC-85 and NSW elements train and specialize in special operations missions as well as being deployed in support of each other. The concept has proved very successful with a pool of seasoned aviators with extensive SO experience who solely focused on SO, SOF support.

The Marine Corps and MARSOC do now have a relationship where a tasked Marine squadron provides direct support (DS) or specializes in SO mission to MARSOC. The concept has worked operationally during combat SO HAF missions but has not cemented any type of relationship. The Marine Corps was able to create a tailored assault support element that was comprised of Marine Corps CH-53s that were escorted by Marine Corps AH-1s. The assault support and escort element was scalable depending on the size of assaulters. The Marine Corps provided overall command and control through the fixed wing Harvest Hawk (KC-130J) and interoperability between conventional and SOF systems was established in extensive rehearsals. The Intelligence surveillance and reconnaissance (ISR) platforms, Command and Control (C2), Close Combat Attack (CCA), Close Air Support (CAS), and the assault support elements will all be comprised of Marine Corps air assets. Marine Corps aviation possesses the required assault support, escort, attack helicopter, fixed wing C2, sensors and payloads needed for world class HAF operations. The Marine Corps would gain from aligning a HAF squadron that provided DS to MARSOC and other SOF elements. This relationship would be mutually beneficial and

2112 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

strengthen each other's ability to integrate and increase special capabilities. A dedicated HMLA would be similar to the navy-NSW HSC model where a Marine squadron would specialize and maintain resident knowledge on SO missions and SOF tactics. The Marine Corps could dedicate two HMLAs (one to each coast) and concentrate its highly skilled aviators to these units for high risk mission and building inherent trust into a relationship between MARSOC and Marine Corps aviation planners and operators.

MAGTF-SOF I-3: MAGTF-SOF Capabilities, USMC Assists with SOF Core Tasks, MAGTF-SOF Digital Systems Interoperability and Operations/Intelligence Fusion

Integrating MAGTF-SOF Capabilities: The Marines Corps and US SOF are naturally aligned in terms of mission approach and execution. Both are forward-deployed in similar geographical areas, both are actively engaged in shaping operations and are able to respond immediately to crises with a tailored response, and perform operations in an enduring campaign. The MAGTF possesses powerful capabilities that complement SOF operations.[18] Marines and SOF can combine their unique mission orientations and approaches to be better postured to defeat the modern enemy operating around the globe. The effectiveness of this combined force of Marine and SOF interconnectedness must be strengthened, expanded, and formalized to better support geographic combatant command (GCC) requirements.[19]

Forward-deployed MAGTFs and MARSOF, operating within the same region, provide increased opportunity for interoperability between the Marine Corps and the special operations community.[20] A forward-deployed SOF, with an established footprint, communicates the

[19] U.S. Marine Corps. *United States Marine Corps and United States Special Operations Command Concept for Integration, Interdependence, and Interoperability.* Washington, DC.)28 July 2017): 2.
[20] U.S. Marine Corps. *Marine Corps Special Operations,* MCWP 3-05. Washington, DC. (1 June 2017): 8-2.

evolving situation to the MAGTF, which provides a sustained national response.[21] SOF access and relationships present significant advantages for the integrated Marine and SOF team. This access and relationships give Marine Corps forces the visibility on crisis response or plans the Theater Special Operations Command (TSOC) is working on in support of the GCC.[22] This allows the Corps to suggest ways that Marines could support such plans, ideally in an integrated manner.

SOF and CF often share the same operational areas for extended periods when they are mutually reliant on each other's capabilities. SOF-CF synchronization facilitates unity of effort and maximizes the capability of the joint force which allows the Joint Force Commander (JFC) to optimize the principles of joint operations in planning and execution.[23] MAGTFs also execute phase zero operations or respond to crises, often without the advantage of local area knowledge and preexisting relationships. USSOCOM's global presence and foreign partnerships developed with strong language and cultural expertise, are critical to working with the local populace and security forces and can assist the MAGTF.

USMC assists with SOF core tasks: The GCCs are increasing their demand for tailored forces to conduct Theater Security Cooperation (TSC) activities with a wider number of partner nations. Security Force Assistance (SFA), joint combined exercise training (JCET), and phase zero activities are important elements for both the Marine Corps and MARSOC's engagement strategy and the GCC's theater campaign planning. These activities ensure access prior to the start of contingencies and contribute directly to the reduction of ungoverned spaces from which

2114 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

future adversaries may originate.[24] The Marine Corps must develop additional opportunities for regional rotational training bases that improve interaction with partner militaries, increase regional knowledge and keep Marines forward deployed. The Marine Corps and MARSOC would benefit from partnering during these types of rotations by deploying to similar regions and working together while deployed. Security cooperation and Marine Corps train and assist units could reduce the redundancy by partnering with MARSOC regional security elements.

Prior to MARSOC, the Marine Corps conducted Foreign internal defense (FID) and SFA through the Foreign Military Training Unit (FMTU). The FMTU structure and personnel were used to create the Marine Raider Regiment staff and a third Marine battalion that was known as the Marine Special Operations Advisory Group (MSOAG). Since then the Marine Corps has not fully re-established a robust ability to conduct FID and SFA. Several units exist in the Marine Corps that conduct special operation type missions and train to SOF core capabilities. Following FMTU becoming part of MARSOC, the Marine Corps Training and Advisory Group (MCTAG) and Marine Corps Security Cooperation Education and Training Center (SCETC) filled the Marine Corps role in security cooperation (SC) programs around the globe. Both Marine units combined in 2011 to create the Marine Corps Security Cooperation Group (MCSCG). Globally, Marine Corps personnel deploy to conduct similar missions as their MARSOC counterparts. Both units include advisor skills, training and assessment expertise, and security assistance program management with the major difference being in training, equipment, funding, and authorities. The MCSCG mission is to execute and enable SC programs, training, planning, and activities in order to ensure unity of effort in support of our Corps and Regional Marine Component Command (MARFOR) objectives, and in coordination with operating forces and

[24] United States Marine Corps, Combat Development and Integration, *Expeditionary Force 21 – Forward and Ready: Now and in the Future*, March 2014, Pg. 9.

2115 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

MAGTFs. MARSOC and MCSCG would greatly benefit from assisting one other. The Marine Corps should increase MCSCG overall staff and missions. There are numerous SC missions that are designated as SOF missions that are unable to be filled due to the shortfall in US SOF. MCSCG could work with MARSOC to conduct supporting and geographically connected missions. This would allow for shared training, culture and regional expertise and increased involvement with CF and SOF during deployment area of operations.

MAGTF-SOF digital systems interoperability and operations/intelligence fusion: Interoperability is a lower state of SOF-GPF interaction than integration. CF and SOF often use different digital systems from radios to computer systems. Integration can be achieved in the absence of interoperable systems. MARSOC and the Marine Corps should seek interoperable systems or train to share information. Because MARSOC must work with both USSOCOM and Marine Corps units, it is important to understand each other's systems. MARSOC must lead the way on digital systems interoperability and seek like systems or work arounds. Interoperability of systems lowers the barriers to integration and reinforces the shifts in thinking, operations, and culture described above.[25]

MARSOC-USMC I-3 in Common Operating Areas: Liaison Elements Between SOF and USMC, Sharing Geographic Alignment Responsibilities

Strengthen Liaison Elements between SOF and USMC: Liaison between SOF commands and the Marine Corps has improved over the last ten years. For starters, the Marine Corps has been involved in using the special operations command and control element (SOCCE) as a critical point for SOF-CF coordination and synchronization of special operations activities

[25] Schroden, Jonathan, David Broyles, Vera Zakem, Jerry Meyerle, and Ryan Evans. *Improving SOF-GPF Integration for Crisis Response: An Action Plan for HQMC and SOCOM.* Center for Naval Analyses, Arlington, VA. (December 2015): 13.

with other joint operations. The SOCCE is normally employed when SOF conducts operations in support of a CF. It performs C2 or liaison functions according to mission requirements and as directed by the establishing SOF commander.[26] Since MARSOC was established, the SOF Liaison Element (SOFLE) has evolved to be more than a task organized rotational SOF element deployed within a specific nation or embedded within CF to conduct liaison activities to a permanent liaison within Marine Corps organizations. The SOFLE is tasked with coordination, assessing, and recommending training, equipping, and engaging opportunities with host nation (HN) forces or provide connectivity and synchronization of expeditionary forces.[27] Having a permanent SOFLE on Marine Expeditionary Units (MEU) was created by the USSOCOM Commander and the Commandant of the Marine Corps (CMC) to facilitate greater cooperation between SOF and Marine forces.[28] This greater cooperation was successful in the integration of Marines and SOF through the deployment of a SOFLE with Amphibious Readiness Groups (ARG)/MEUs.[29] The first ARG/MEU SOFLE conducted a workup and deployed with the 11 th MEU in July 2014 and continues to today with each east and west coast MEU. The SOFLE provides the critical links to the SOF network, the TSOC forward-deployed SOF elements, and interagency partners. Collaboration between SOF and Services will facilitate cross-organizational knowledge and communication for dynamic responses to rapidly evolving events.[30] To demonstrate the importance of the SOFLE, in 2017, the USSOCOM commander made the program an operational requirement. The SOFLE program has been a wide success for the Marine Corps as well. Theater Special Operation Commands (TSOC) have increased their

2117 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

need for Marine MEU aviation, logistics and intelligence support. MARSOC has trained all SOFLEs since it was created. The Marine Corps has reciprocated this by placing a "Marine liaison element" (MARLE) in the TSOC.[31] This has allowed the Marine Corps to provide more responsive and tailored, MAGTF centered, crisis response options to the TSOC.

MARSOC can further integrate with the USMC by placing liaisons at various MAGTFs. SOF liaison elements at CF headquarters play a critical role in SOF-CF I-3.[32] The Marine Expeditionary Brigade (MEB) and the USMC's Special Purpose MAGTFs for crisis response (SPMAGTF-CRs)[33] would be ideal due to similar training and capabilities. Liaison elements could help mitigate the lack of trusted relationships, SOF misunderstandings and could help educate MAGTF leaders on how to utilize SOF as an additional option or capability.

Sharing Geographic Alignment Responsibilities: The Marine Corps and MARSOC have yet to align forces in support of each other's geographic expertise. The Marine Corps has cultural, language, intelligence and tactical expertise within each Marine Expeditionary Force (MEF) that could benefit from the current geographic alignment of MARSOC's construct. MARSOC remains tied in some way to a region through an established partner force either for a long period of time. A MEF and an Marine Raider Battalion (MRB) can begin habitual relationships that support each other through training and operationally. Due to MARSOC's enduring commitment to several partner forces and expertise in several regions of the world, increased integration of Marine Corps forces into these geographic areas would be mutually beneficial. Talks must begin between the MEF and MARSOC commanders and their staffs to

2118 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

begin coordination between MRBs and USMC general purpose force (GPF) battalions conducting these deployments. These relationships facilitate the involvement of MARSOC and MEF units (SPMAGTFs and MEUs) in each other's pre-deployment training and work-up cycles (MARSOF play in the MEU certification exercise (CERTEX) and USMC GPF observation of the MARSOC RAVEN exercises).[34]

I-3 through Intelligence: Enhanced Concept of Intelligence, Electronic Warfare (EW) Capabilities Gap, Networking for Rapid/Precise Fires, USMC and MARSOC Theater ISR

Enhanced Concept of Intelligence: Future forces will increasingly rely on sensors, networks, architectures, and tradecraft to establish and maintain situational awareness, influence the operating environment, and support decision-making at higher headquarters and on down to the point of action. The MAGTF must complement this with information harvested from commercial and social information sources. A deeper understanding of the environment developed from the collected observations, information, and experiences of Marines up and down the echelons of the force. MARSOC and Marine Corps elements must seek to capture the value of pushing networked intelligence down to tactical units.

Intelligence sharing between the Marine Corps and MARSOC is a requirement in order to maintain an edge on future threats. Marines and SOF have access to formidable operational, theater, and national intelligence capabilities. Both the MAGTF and SOF are equipped to generate tactical intelligence but require reach-back support for analytical depth and capacity. With its robust communications and ISR architecture, a MAGTF not only can generate a multi-

[34] Schroden, Jonathan, David Broyles, Vera Zakem, Jerry Meyerle, and Ryan Evans. *Improving SOF-GPF Integration for Crisis Response: An Action Plan for HQMC and SOCOM.* Center for Naval Analysis, Arlington, VA. (December 2015): 12.

DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

source, multi-discipline intelligence picture organically, but also possesses a robust reach-back capability through the Marine Corps' Intelligence, Surveillance, and Reconnaissance Enterprise (MCISRE) that provides ready access to a broad range of Service and Intelligence Community resources.[35] MCISRE and the Marine Corps can further develop a better relationship with USSOCOM through MARSOC. No agency or service has sufficient ISR capacity and would benefit by assisting each other.

Preparation of the environment and phase zero operations are integral to both SOF and CF. SOF conducts preparation of the environment prior to the arrival of follow-on force[36] and has significant organic all source intelligence collection assets as well as a robust reach back capability that extends into all intelligence agencies within the US. Special operations forces take actions to prepare the operational environment for potential operations by various means but in many cases overlap with Marine Corps intelligence collections. SOF focuses on preparation of the environment (PE) during the shaping phase of an operation, as well as developing and preparing for the entry of conventional forces. SOF also supports agencies that resolve conflicts using either lethal or nonlethal action. SOF are usually located within an area and assigned to conducting PE. CF also play a large role in supporting PE through supporting special operations advance force operations (AFO). CFs are also forward-deployed or stationed in areas to conduct PE either alone or along with SOF. AFO encompasses many PE activities, but are intended to prepare for near-term direct action. The MAGTF along with several specialized units within the Marine Corps could greatly assist or take the lead on PE activities. Special operations AFO may include, but are not limited to, close target reconnaissance; tagging, tracking, and locating (TTL);

[35] U.S. Marine Corps. *United States Marine Corps and United States Special Operations Command Concept for Integration, Interdependence, and Interoperability.* Washington, DC. (28 July 2017): 9.
[36] U.S. Joint Staff. *Joint Publication 3-05 - Special Operations.* Washington, DC. 16 July 2014: II-4.

reception, staging, onward movement, and integration of forces; infrastructure development; and terminal guidance.[37]

The Electronic Warfare (EW) Capabilities Gap: Manned and UAS payloads can be equipped to support MAGTF and SOF operations**.** The Marine Corps will incorporate an EW capability into current and future UAS platforms as EA-6B Prowlers are being phases out. The Marine Corps addresses EW requirements through an approach called MAGTF EW where an integrated, platform-agnostic, EW capabilities, can be placed on manned and unmanned assets. The Marine Corps' vision is on developing a system or using existing systems like the Intrepid Tiger II (ALQ-231) that can be placed on any manned or unmanned aviation platform in the Marine Corps. Electronic Warfare Service Architecture (EWSA) allows data exchange and hardware protocol intended to connect EW/SIGINT airborne nodes to ground operators, Cyberspace and Electronic Warfare Coordination Cells (CEWCCs), and other air EW nodes. MARSOC and MAGTF operations can use the EWSA and have "on-demand EW fires" in operational conditions under CEWCC control, and will unite Air EW, Ground EW, and SIGINT via an adaptive network with multiple waveforms.[38]

Networking for Rapid/Precise Fires: In future conflicts MARSOC and the Marine Corps will operate against adversaries with effective ISR and the ability to place long-ranged fires both with precision and for massed effects. In the current fight with Islamic State (IS) both SOF and CFs have fought against an enemy with these capabilities. SOF depend on unmanned aircraft (UA) with imagery, signal intelligence (SIGINT), and other intelligence collection capability to provide persistent, high-fidelity intelligence on an adversary that moves and

2121 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

operates among civilians.[39] Marine Corps units will have to learn to train and operate these capabilities down to the lowest level as MSOTs have been doing since their existence. MARSOC and the Marine Corps must acquire means to interdict and destroy enemy UAS capabilities. This shortfall effects both SOF and conventional forces. The Marine Corps and MARSOC must partner to integrate testing teams that explore ways to defeat enemy UAS capabilities.

The find, fix, finish, exploit, analyze and disseminate (F3EAD) model that was developed over the past several years of conflict serves to fully integrate intelligence and SOF operations in a continuous ISR and targeting cycle.[40]Airborne ISR, specifically full motion video (FMV) and SIGINT, is essential to COIN and counter-network operations. Outside of SOF it is clear that services are behind in providing adequate resources to deployed forces. The Marine Corps would benefit in purchasing similar program of record small and tactical UAS platforms. Airborne ISR is most effective when it is massed, synchronized with operations, integrated with all-source intelligence, and employed under a unity of organization. Forward deployed SOF and CFs must have forward processing, exploitation, and dissemination (PED) integrated into the Tactical Operations Center (TOC). MARSOC does not currently possess a system can PED and is integrated into a TOC. MARSOC must continue to develop this capability within each Marine Special Operation Company (MSOC). Marine Corps infantry units must have this capability at the infantry battalion level with the capability to conduct operations out of each company. This will require significantly increasing the personnel trained in managing ISR, purchasing appropriate level unmanned aerial systems (UAS), and establishing fully integrated TOCs. Airborne ISR is the centerpiece of the F3EA because it is tightly synchronized with a finishing

2122 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

force.[41] Marine aviators that fill the role of forward air controllers (FAC) within MARSOC and the Marine Corps down to the MSOC and infantry battalions are ideal for managing small and tactical UAS programs. This includes the ordering, training and sustaining of the personnel and equipment. To further integrate UAS operations into MARSOC and Marine Corps operations, the FAC should be used as a vital part of the company or battalion operations section. MARSOC is set to expand its UAS personnel by integrating permanent Unmanned Aerial Vehicle (UAV) military occupation specialty (MOS) trained Marines. These MOS trained UAV operators can be pushed down to the MSOC level and further deliver UAS support to operations.

USMC and MARSOC theater ISR: MARSOC and the Marine Corps have been working on ways for conventional Marine Unmanned Aerial Vehicle Squadrons (VMU) to support SOF operations through their various UAS platforms. The concept yielded negative results over the last two years but serves as an excellent starting point. Although the initial idea seemed to be sound, the VMU squadrons were too large and burdensome to support SOF effectively. The large footprint, in addition to the unrealistic force protection requirements, poor sensors, and limited flight hours made integration difficult.

The difficulty in integrating the VMU to support MARSOC does not negate the need for MARSOC and the Marine Corps to have an organic capability that can provide full motion video (FMV) processing, exploitation, and dissemination collaboration (PED) capability that supports the MAGTF, MARSOC, and the joint force. MARSOC units did not gain from having the VMU support and were able to address the UAS problem with organic and purchased small UAS (SUAS) and tactical UAS (TUAS) managed internally to the MSOC. Outside of the VMU, ISR was supplemented with contracted ISR that required little to no footprint, had more advanced

[41] Flynn, Michael T, Rich Juergens, and Thomas L. Cantrell. "Employing ISR: SOF Best Practices" *Joint Force Quarterly*, 50, 3rd Quarter (2008): 61.

2123 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

payloads and could fly additional hours. Lastly, MARSOC gained from the sourced conventional and SOF specific theater ISR that was far superior to the VMU capabilities. The support relationship that existed between the VMU and MARSOC forward deployed units was an excellent start, however, inferior sensors and the reasons listed earlier have slowed progress. Since the Marine Corps' entry into Operation Iraqi Freedom (OIF), and Operation Enduring Freedom (OEF), and now Operation Inherent Resolve (OIR) the demand for dedicated unmanned aerial reconnaissance systems has grown exponentially. ISR collections through organic UAS has played a critical part in supporting the MAGTF's aerial reconnaissance requirement as well as other missions such as communications relay and Signals Intelligence (SIGINT) collections.[42] For starters, the Marine Corps or MARSOC must purchase its own theater level UAS unit. Currently, the Marine Corps only operates TUAS (RQ-7B Shadow), Small Tactical UAS (STUAS) (MQ-21A Blackjack), and various SUAS (RQ-11B Raven, RQ-20 Puma and Wasp IV). In 2013, United States Special Operations Command upgraded to the MQ-1C Grey Eagle and is operated under the Special Operations Aviation Regiment (SOAR). The added range, endurance, and available payloads provides a capability that directly supports the service. MARSOC does not possess the structure to support the MQ-1C but VMU squadrons are capable of supporting a more capable system than they currently field. The Marine Corps is far behind all other services on group 4/5 UAS. An upgraded VMU could provide an added fires and collection capability for the MAGTF and MARSOC.

In the interim, MARSOC and the Marine Corps have purchased a group 2 SUAS that will be utilized by both elements. Although the Stalker XE (SUAS) is not a group 4/5 UAS it is a very capable system and is a step in the right direction in I-3 and a more advanced and capable

[42] Marine Corps Concepts and Programs, "Unmanned Aerial Systems," *Marine Corps Concepts and Programs*, accessed December 2017, https://marinecorpsconceptsandprograms.com/programs/aviation

2124 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

UAS. The Stalker XE is already being field in both MARSOC and the Marine Corps. The system boasts longer endurance (playtime) than any current SUAS, low altitude silent operations, and it can be equipped with several multi-function, plug and play payloads. The most important feature is its ability to broadcast its signal beyond the tactical UAS operator and into a TOC to give decision makers better situational awareness, shorten the kill chain or develop targets and patterns of life all real time.

Training: Urban Operations and Complex Terrain, Expeditionary Logistics

Urban Operations and Complex Terrain: The Marine Corps is experimenting with new equipment, structing, and training that better prepares the Marine Corps to fight in the future operating environment within urban areas and complex terrain. The Marine Corps Warfighting Laboratory (MCWL) has spearheaded this effort with the Marine Corps Force 2025 (MCF 25) to ensure the MAGTF is postured to address the challenges of the future operating environment. Sea Dragon 2025 (SD 25) takes MCF 25 and creates an experiment roadmap to build an expeditionary force for the 21st century. SD 25 focused on the Marine Corps Force 2025 (MCF 2025) infantry battalion. Most of the equipment that was used to equip the infantry battalion is already been used by SOF. The Marine Corps would have benefited from integrating MARSOC into the training of this phase to give the Marine Corps a better understanding of what it takes to train, equip, and sustain these skills and advanced equipment. Lessons learned in MARSOC over the last ten years would have assisted in this effort.

The next phase of SD 25 will include dynamic concurrent experiment efforts focused on dense urban operations, 21st century fires, an adaptive threat force, and the continuation of the Marine Corps Experiment Operational Advisory Group (EXP OAG). All of these efforts must be integrated with MARSOC. Both elements are trying to solve the same problems by using

2125 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

emerging concepts and technologies. This next phase of SD 25 has already started focusing on the MAGTF hybrid logistics and will proceed with information environment operations, and EAB operations. MARSOC and the Marine Corps must employ this concept for I3 during the remainder of SD 25.

Expeditionary Logistics: As described above, MCF 25 is addressing the logistics challenges of operating within the future operating environment through hybrid logistics experimentations. The Marine Corps is working to adopt a "hybrid" approach to expeditionary logistics that leverages the rapid development of unmanned/autonomous logistics systems, additive manufacturing, and "smart" logistics information technologies to support a widely distributed force in an anti-access/ area denial (A2/AD) environment. Combat Logistics Battalions (CLB) 8 and 6 are serving as the USMC FY18 experiment forces and support live-force experiments. The focus will focus on tactical-to-strategic logistics in contested environments. This is another area where MARSOC and the Marine Corps must work together. Lastly, this portion of MCF 25, hybrid logistics also focuses on the medical support in these same environments.[43] The MAGTF and this increased medical support is another way the Marine Corps can provide added support to SOF forward-deployed units.

Part 3: MARSOC-Interagency I-3

MARSOC must be as comfortable working as a part of interagency or multinational efforts when serving inside of a Raider formation.[44] SOF, as part of the Joint, Interagency, Intergovernmental and Multinational (JIIM) network, must be increasingly flexible, agile, and capable of integrating operations across national and GCC seams to effectively neutralize threats

[43] Marine Corps Warfighting Laboratory, "Sea Dragon 2025 Assessment Conference." *Marine Corps Warfighting Laboratory*, accessed December 2017, http://www.mcwl.marines.mil
[44] U.S. Marine Corps Special Operations Command. *Marine Special Operations Forces (MARSOF) 2030 (Draft not approved).* Stone Bay, NC. (January 2018): 10.

to US interests.[45] Policy objectives are only achieved by the integration of JIIM partners' capabilities focused toward shared objectives and common goals. Understanding this, SOF will execute Integrated Campaigning as part of a larger JIIM team to achieve the Central Idea of this concept.[46]

To achieve greater collective JIIM agility and flexibility, MARSOC will formally embed and exchange liaison elements with an evolving list of partners to achieve an unprecedented degree of understanding and capability for integrated action. MARSOC will modify organizations to ensure that each liaison element is properly structured and manned by SOF personnel with the education and experience to be valuable, productive contributors to partner organizations while advancing and protecting US interests globally.[47] Interagency interaction facilitates our development of Regional SOF Coordination Centers (RSCCs). These multilateral coordination forums established in key locations around the world are to promote multinational collaboration, education and training opportunities with partner nation SOF. RSCCs shall facilitate long-term relationships and burden-sharing to achieve mutual security objectives.[48] In order to expand the global SOF network for MARSOC, there must be better efforts to increase interagency liaisons and establish a further commitment to Irregular Warfare (IW) and specifically Unconventional Warfare (UW).

Increase interagency liaisons: MARSOC personnel must increase interagency billets along with increasing interagency partners brought in to fill billets within MARSOC. The most common way to achieve this is through increasing interagency liaisons through Special Operations Support Teams (SOST). USSOCOM elements in the national capital region (NCR)

[45] U.S. Special Operations Command. *Special Operations Forces Operating Concept.* Tampa, FL. (1 February 2016): 2.
[46] Ibid., 3.
[47] Ibid., 7.
[48] U.S. Special Operations Command. *SOCOM 2020: Forging the Tip of the Spear.* MacDill AFB, FL. (2013): 6.

2127 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

facilitate interagency coordination between SOF and other interagency partners, and are a major element in the global SOF network that enables interagency coordination overseas. MARSOC must fill all current SOST billets and expand to additional agencies. Special operations support teams (SOSTs) are cornerstones of the USSOCOM. MARSOC Special Operations Officer (SOO) career path must allow for short rotations to fill SOST billets and encourage participation for O-4 and O-5s and sending quality officers to represent MARSOC. The key hurdle in filling critical interagency liaisons is still availability of MARSOC personnel.

The Interagency Partnership Program (IAPP) is the methodology for providing on-site facilitation of DoD planning with other USG departments and agencies for global operations against terrorist networks. The IAPP supports intergovernmental agency information sharing, improves security situational awareness, and builds a teamwork approach to unified security activities. SOSTs are USSOCOM representatives embedded with the NCR HQ of interagency partners to foster interagency coordination and collaboration. MARSOC would greatly gain from aligning the activities of SOF with USG functional lines of effort through additional liaisons. USSOCOM elements in the NCR are a major element in part of the global SOF network that strengthens the relationships of SOF with USG departments and agencies and other organizations.[49] Unconventional warfare requires significant interagency participation because the activity includes support to both the military and political aspects of internal opposition.[50]

MARSOC's further commitment to Irregular Warfare: If MARSOC is going to take a more active role in the support to UW it must advance its strategic partnership with the Central Intelligence Agency (CIA). MARSOC planners and operations officers must be better integrated

[49] U.S. Joint Staff. *Joint Publication 3-05 - Special Operations.* Washington, DC. 16 July 2014: III-22.

2128 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

within the CIA to enable collaborative planning and execution of IW and UW activities. The CIA's intelligence activities that are authorized under Title 50 and MARSOC's military activities authorized under both Title 10 and Title 50 provide mutually supporting, not mutually exclusive, authorities. This provides a unique construct from which CIA and MARSOC planners can collaborate and complement unconventional options for national security needs.[51]

The CIA and the Marine Corps have been successful in partnering in unconventional warfare operations through counterinsurgency operations in Vietnam in programs like the Provincial Reconnaissance Units (PRU). PRUs were under the operational control of the CIA relied on specialized military teams from special operations and conventional units to conduct their unconventional recruiting, training and operations. The CIA drew upon service special operation units and Marine expertise in training, language skills, cultural and political understanding, and access and placement to be effective. Likewise, MARSOC still maintains MSOTs and MSOCs with a depth of knowledge on unconventional warfare both in training and practice. The CIA and MARSOC should establish a partnership that enables the CIA to utilize MARSOC elements in support of their UW operations.

Commander, United States Special Operations Command has assigned Commander, Marine Forces Special Operations Command (COMMARFORSOC) the following SOF core activities: direct action (DA), special reconnaissance (SR), counterterrorism (CT), foreign internal defense (FID), security force assistance (SFA), counterinsurgency (COIN), support to CWMD, and support to UW.[52] MARSOC is too small to be an expert at all of its core assigned tasks or to be the proprietor of several tasks. Instead MARSOC should further establish its role in

2129 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

irregular warfare by specializing in certain aspects. Once considered largely the province of special operations forces (SOF), irregular threats are now understood to fall within the purview of the entire joint force. To prevent, deter, disrupt, and defeat irregular threats, the U.S. military will apply some blend of counterterrorism, unconventional warfare, foreign internal defense, counterinsurgency, and stability operations. MARSOC must first collaborate with other governmental agencies, multinational partners to understand the situation in depth, act in concert, and continually assess and adapt their approach in response to the dynamic and complex nature of the problem. Unconventional warfare must be the cornerstone of MARSOC's core tasks.

Unconventional warfare operations span from support to groups resisting government authority to the overthrow of the government. Department of Defense (DoD), Department of State (DoS), and other interagency partners evaluate diplomatic, environmental, and economic costs and benefits prior to recommending UW operations but SOF usually conducts UW operations because of its size and forces trained in UW. These UW operations present significant risks, but they can also help resolve international crises without overt, large-scale CF. Resistance movements and insurgencies commonly organize around interrelated elements of an underground, an auxiliary, and a guerrilla force.[53] By partnering with all US government agencies that plan for UW operations, MARSOC will be best suited to conduct and execute UW operations. UW activities are conducted in support of a resistance or insurgency in a denied area. The initial focus of UW activities in support of an opposition is typically conducted in areas or environments where the governing authority has the capacity to deny overt freedom of action to the opposition and is best suited for SOF. UW operations rely on synchronization of SOF and CF and unified action with one or more interagency and multinational partners.[54]

[53] U.S. Joint Staff. *Joint Publication 3-05 - Special Operations.* Washington, DC. 16 July 2014: II-8.
[54] Ibid., II-8.

Conclusion

In the "Age of Everything," MARSOC will be required to develop, strengthen and build increased integration, interoperability, and interdependence (I-3) between the Marine Corps (MARSOC-USMC I-3) and its interagency partners (MARSOC-interagency I-3).

The concept above outlines several key MARSOC-USMC I-3 concepts such as potential Marine air integrating with SOF for specific crisis response operations and the establishment of relationships to conduct SOF training and operations. Globally integrated operations will encourage collaboration across the Joint Force and with partners. These operations allow stakeholders to bring differing perspectives and capabilities to bear on complex challenges.[55] There is also an opportunity for increased I-3 in commonalities between MAGTF and MARSOC capabilities, intelligence collection and capabilities and both training and operationally.

MARSOC can also increase I-3 within the vast interagency organization and expanding the global SOF network. The complexity of a FOE requires a wide range of interagency and allied partners to understand and an even larger network of capabilities to address.[56] This will require MARSOC to establish better interagency partnership. This can be accomplished through increasing interagency liaisons both inside and outside of MARSOC. Lastly, MARSOC must establish a deeper commitment to Irregular Warfare (IW) and within further develop an enduring relationship with the interagency partners that conduct and assist in IW.

DEFENSE ACQUISITIONS

Assessments of Selected Weapon Programs

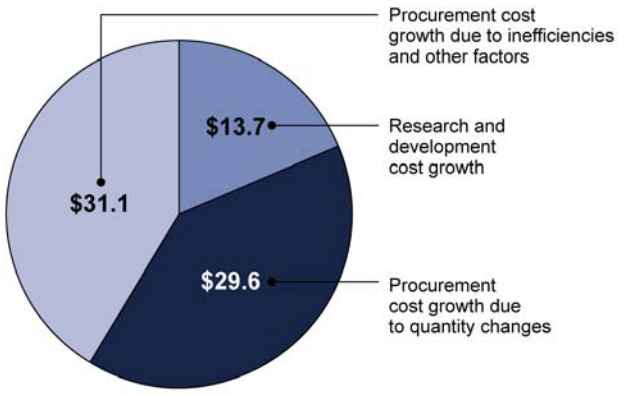
GAO Highlights

Accountability * Integrity * Reliability

Highlights of GAO-12-400SP, a report to congressional committees

Why GAO Did This Study

This is GAO's annual assessment of DOD weapon system acquisitions, an area that is on GAO's high-risk list. The report is in response to the mandate in the joint explanatory statement to the DOD Appropriations Act, 2009. It includes (1) observations on the cost performance of DOD's 2011 portfolio of 96 major defense acquisition programs; (2) an assessment of the knowledge attained by key junctures in the acquisition process for 37 major defense acquisition programs, which were selected because they were in development or early production; (3) observations on the implementation of acquisition reforms, particularly for 16 future major defense acquisition programs that are not yet in the portfolio, which represent the best opportunity to assess DOD's progress in this area. To conduct this review, GAO analyzed cost, schedule, and quantity data from DOD's Selected Acquisition Reports and collected data from program offices on technology, design, and manufacturing knowledge; the use of knowledge-based acquisition practices; and the implementation of DOD's acquisition policy and acquisition reforms. GAO also compiled individual assessments of 68 weapon programs. Selection factors include major defense acquisition programs in development or early production, future programs, and recently cancelled programs.



DOD agreed that cost growth has occurred, but did not fully agree with our metrics for measuring cost growth, stating that they did not adequately address when, why, and how it occurred. GAO believes the report directly addresses these distinctions.

View GAO-12-400SP. For more information, contact Michael J. Sullivan at (202) 512-4841 or sullivanm@gao.gov.

What GAO Found

The total estimated cost of the Department of Defense's (DOD) 2011 portfolio of 96 major defense acquisition programs stands at $1.58 trillion. In the past year, the total acquisition cost of these programs has grown by over $74.4 billion or 5 percent, of which about $31.1 billion can be attributed to factors such as inefficiencies in production, $29.6 billion to quantity changes, and $13.7 billion to research and development cost growth. DOD's portfolio is dominated by a small number of programs, with the Joint Strike Fighter accounting for the most cost growth in the last year, and the largest projected future funding needs. The majority of the programs in the portfolio have lost buying power in the last year as their program acquisition unit costs have increased. The number of programs in the portfolio has decreased from 98 to 96 in the past year and, looking forward, is projected to decrease again next fiscal year to its lowest level since 2004.

Cost Growth over the Past Year for DOD's 2011 Portfolio of Major Defense Acquisition Programs (Fiscal Year 2012 Dollars in Billions)

Source: GAO analysis of DOD data.

In the past 3 years, GAO has reported that newer programs are demonstrating higher levels of knowledge at key decision points. However, most of the 37 programs GAO assessed this year are still not fully adhering to a knowledge-based acquisition approach. Of the eight programs from this group that passed through one of three key decision points in the acquisition process in the past year, only one—Excalibur Increment Ib—implemented all of the applicable knowledge-based practices. As a result, most of these programs will carry technology, design, and production risks into subsequent phases of the acquisition process that could result in cost growth or schedule delays.

GAO also assessed the implementation of selected acquisition reforms and found that most of the 16 future programs we assessed have implemented key provisions of the Weapon Systems Acquisition Reform Act of 2009. Programs have also started to implement new DOD initiatives, such as developing affordability targets and conducting "should cost" analysis. Finally, as could be expected from the increased activity early in the acquisition cycle, the 16 future programs we assessed are planning to spend more funds in technology development than current major defense acquisition programs.

I am pleased to present GAO's annual assessment of selected weapon programs. This report provides a snapshot of how well the Department of Defense (DOD) is planning and executing its major defense acquisition programs—an item on GAO's high-risk list and an area that we have identified as having the potential for significant cost savings in our first two reports on *Opportunities to Reduce Potential Duplication in Government Programs, Save Tax Dollars, and Enhance Revenue*.[1] This year's report offers observations on the performance of DOD's $1.58 trillion portfolio of 96 major defense acquisition programs. These observations serve as measures of DOD's progress in managing weapon system cost growth and as indicators of potential challenges. This year's report also includes assessments of the risks on 68 individual weapon programs. These assessments can assist DOD and Congress in making decisions about the programs they approve and fund in a budget-constrained environment. When we issued our first annual assessment in 2003, it included 26 defense programs ranging from the Marine Corps' Advanced Amphibious Assault Vehicle to the Missile Defense Agency's Theater High Altitude Area Defense system. This edition still includes eight programs that appeared in the 2003 report, which is indicative of the lengthy development times and acquisition challenges that DOD has faced over the last 10 years.

Since we began issuing this report, Congress and DOD have made noteworthy improvements in the legal and policy frameworks that govern weapon system acquisitions by mandating and encouraging a more knowledge-based approach to the development and production of major systems. These changes have led to some improvement in the knowledge attained by programs at key points in the acquisition process, but more still needs to be done. Practice has lagged behind policy in certain areas and we have not yet seen improvements in outcomes that are commensurate with the improvements in law and policy. In our review this year, we found

[1]GAO, *High Risk Series: An Update*, GAO-11-278 (Washington, D.C.: Feb. 16, 2011); GAO, *Opportunities to Reduce Potential Duplication in Government Programs, Save Tax Dollars, and Enhance Revenue*, GAO-11-318SP (Washington, D.C.: Mar. 1, 2011); GAO, *Follow-up on 2011 Report: Status of Actions Taken to Reduce Duplication, Overlap, and Fragmentation, Save Tax Dollars, and Enhance Revenue*, GAO-12-453SP (Washington, D.C.: Feb. 28, 2012).

2141 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

that the cost to develop and produce DOD's current portfolio of major defense acquisition programs grew by over $74.4 billion, of which about $31.1 billion can be attributed to factors such as inefficiencies in production, $29.6 billion to quantity changes, and $13.7 billion to research and development cost growth. The implementation of knowledge-based acquisition practices that might prevent or mitigate the potential for cost growth has been uneven across the portfolio. For eight programs that passed through one of three key decision points in the acquisition process this year, only one implemented all of the applicable knowledge-based practices. As a result, most of these programs will carry technology, design, and production risks into subsequent phases of the acquisition process that could result in cost growth or schedule delays.

There have been some positive developments, especially with regard to DOD's future major defense acquisition programs, which are now approaching system development or will bypass system development for production. We found that most of these future programs are implementing acquisition reforms, such as competitive prototyping, early systems engineering reviews, and acquisition strategies ensuring competition or the option of competition, which have the potential to reduce risk and improve outcomes. Some of these activities require higher upfront investments in systems engineering and other areas to reduce longer term development risk, and it will be important for decision makers to sustain these investments when appropriate, even as DOD's budgetary resources shrink.

Congressional Committees

This is GAO's annual assessment of selected Department of Defense (DOD) weapon system acquisitions, an area that is on GAO's high-risk list. The report is in response to the mandate in the joint explanatory statement to the DOD Appropriations Act, 2009, which requires us to perform an annual assessment.[1] This report provides a snapshot of how well DOD is planning and executing its weapon programs. Congress and DOD have long explored ways to improve the acquisition of major weapon systems, yet programs are still incurring billions of dollars in cost growth. Given the prospect of decreased defense spending, including the possibility of over $1 trillion in sequestration and other budget cuts over the next 10 years, finding ways to prevent or mitigate cost growth is crucial to our national security. In the past 3 years, we have reported improvements in the knowledge that programs attained about technologies, design, and manufacturing processes at key points during the acquisition process. DOD policy and legislation emphasize key knowledge-based acquisition practices; however, we have found that most programs continue to proceed with less knowledge than recommended, putting them at higher risk for cost growth and schedule delays.

This report includes (1) observations on the cost and schedule performance of DOD's 2011 portfolio of 96 major defense acquisition programs, (2) our assessment of the knowledge attained at key junctures in the acquisition process for 37 weapon programs in development or early production, and (3) observations on the extent to which DOD is

[1]See Explanatory Statement, 154 Cong. Rec. H 9427, 9526 (daily ed., Sept. 24, 2008), to the Department of Defense Appropriations Act Fiscal Year 2009, contained in Division C of the Consolidated Security, Disaster Assistance, and Continuing Appropriations Act, 2009, Pub. L. No. 110-329.

2143 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

implementing acquisition reforms, particularly for 16 future major defense acquisition programs.[2]

There are three sets of programs on which our observations are based in this report:

- We assessed all 96 major defense acquisition programs in DOD's 2011 portfolio for our analysis of cost and schedule performance. To develop our observations, we obtained cost, schedule, and quantity data from DOD's December 2010 Selected Acquisition Reports (SAR) and from the Defense Acquisition Management Information Retrieval Purview system. The Ballistic Missile Defense System (BMDS) is excluded from these observations because comparable cost and quantity data are not available.

- We assessed 37 major defense acquisition programs that were mostly between the start of development and the early stages of production for our analysis of knowledge attained at key junctures and the implementation of acquisition reforms. To develop our observations, we obtained information on the extent to which the programs follow knowledge-based practices for technology maturity, design stability, and production maturity using a data-collection instrument. We also submitted a survey to program offices to collect information on systems engineering reviews, design stability, manufacturing planning and execution, and the implementation of specific acquisition reforms. We received survey responses from all 37 programs.

- We assessed an additional 16 future major defense acquisition programs that we selected because they were preparing to enter system development or production. These programs represent the best opportunity to assess DOD's progress in implementing selected acquisition reforms. To develop our observations, we submitted a survey to program offices to collect information on the implementation

[2]Major defense acquisition programs are those identified by DOD that require eventual total research, development, test, and evaluation (RDT&E) expenditures, including all planned increments, of more than $365 million, or procurement expenditures, including all planned increments, of more than $2.19 billion, in fiscal year 2000 constant dollars. DOD has a list of programs designated as pre–major defense acquisition programs (pre-MDAP). These programs have not formally been designated as MDAPs; however, DOD plans for these programs to enter system development, or bypass development and begin production, at which point they will likely be designated as MDAPs. We refer to these programs as future major defense acquisition programs throughout this report.

2144 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

of these reforms and other data and received responses from all the programs.

In addition to our observations, we present individual assessments of 68 weapon programs. Selection factors include major defense acquisition programs in development or early production, future programs, and recently cancelled programs.

We conducted this performance audit from August 2011 to March 2012 in accordance with generally accepted government auditing standards. Those standards require that we plan and perform the audit to obtain sufficient, appropriate evidence to provide a reasonable basis for our findings and conclusions based on our audit objectives. We believe that the evidence obtained provides a reasonable basis for our findings based on our audit objectives. Appendix I contains detailed information on our scope and methodology.

Observations on the Cost Performance of DOD's 2011 Major Defense Acquisition Program Portfolio

The cost of DOD's 2011 portfolio of major defense acquisition programs continues to grow, and the delays in delivering capability to the warfighter have gotten longer. Our analysis of the 96 programs in DOD's 2011 portfolio of major defense acquisition programs allows us to make nine observations.

2145 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Cost Performance Observations

1. The estimated cost of DOD's 2011 portfolio stands at about $1.58 trillion and has grown by over $74 billion or 5 percent in the past year.[a]
2. About $30 billion of this growth can be attributed to quantity changes within major defense acquisition programs; the other $45 billion is due to research and development cost growth and production inefficiencies.[b]
3. Many of the programs in the portfolio with the greatest growth in estimated research and development costs in the last year are already in production and either experienced growth because of lingering development issues or added funding for upgrades or modernization efforts.
4. The cost of the portfolio is driven by the 10 highest-cost programs, which account for 55 percent of its total cost.
5. The Joint Strike Fighter accounts for 21 percent of the total cost of the portfolio and 52 percent, or about $39 billion, of the cost growth in the past year.
6. Ninety-one percent of the funding needed to complete the programs in the portfolio is for procurement, with most of that for a few large programs.
7. Over 60 percent of programs have lost buying power in the last year—as measured by an increase in program acquisition unit cost—depriving DOD of funding that could have been used for additional quantities or other priorities.
8. About 40 percent of the programs have experienced cost increases in the past year that exceed cost growth targets discussed by DOD, the Office of Management and Budget (OMB), and GAO; and over 50 percent exceeded the targets for growth in the past 5 years and since the first full estimate.
9. Looking forward, the number of programs in DOD's 2012 portfolio is projected to be the smallest since 2004 as more programs continue to leave the portfolio than enter it—a positive sign that DOD is adjusting its number of programs to meet resources.

[a]All dollar figures are in fiscal year 2012 constant dollars, unless otherwise noted.

[b]Discussion of growth in the 2011 portfolio does not include BMDS as DOD does not consider adjustments to this system to represent cost growth because the program has been allowed to add 2 years of new funding with each biennial budget. See GAO, *Missile Defense: Actions Needed to Improve Transparency and Accountability*, GAO-11-372 (Washington, D.C.: Mar. 24, 2011) for an assessment of the Missile Defense Agency's (MDA) cost, schedule, testing, and performance progress in developing BMDS.

Additional details about each observation follow.

- **The total cost of DOD's 2011 portfolio of major defense acquisition programs has grown by over $74 billion, or 5 percent, in the last year.** The over $74.4 billion in cost growth over the past year consists of a rise in development costs of $13.7 billion, or 4 percent, and an increase in procurement costs of $60.6 billion, or 5 percent. When

2146 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

measured from their first full estimates, which have been put in place over a number of years, the growth in total acquisition cost for these programs is $447 billion, or 40 percent. In addition, programs continue to deliver capabilities later than anticipated, with the average delay increasing by 1 month in the past year, and averaging 23 months when measured against a program's first full estimate. Table 1 shows the increases in programs' estimated cost and schedule over the last year, and appendix II presents our analysis of cost growth and delays over the past 5 years and against first full estimates.

Table 1: Changes in DOD's 2011 Portfolio of 96 Major Defense Acquisition Programs over the Past Year

Fiscal year 2012 dollars in billions

	Estimated portfolio cost in 2010	Estimated portfolio cost in 2011	Estimated portfolio growth since 2010[a]	Percentage growth since 2010
Total estimated research and development cost	$310	$324	$14	4%
Total estimated procurement cost	1,160	1,221	61	5
Total estimated acquisition cost[b]	1,503	1,578	74	5
Average delay in delivering initial capabilities	—	—	1 month	2

Source: GAO analysis of DOD data.

Note: Figures may not add due to rounding.

[a]The portfolio cost columns do not include the reported cost or cost growth of BMDS. DOD does not consider changes in BMDS costs to represent cost growth because the program has been allowed to add 2 years of new funding with each biennial budget.

[b]In addition to research and development and procurement costs, total acquisition cost includes acquisition-related operation and maintenance and system-specific military construction costs. Details on program costs used for this analysis are provided in app. III.

- **Quantity changes account for almost $30 billion of the nearly $61 billion in procurement cost growth over the last year.** Of the $60.6 billion in procurement cost growth realized in the past year, $29.6 billion

2147 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

is attributable to adjustments in quantities on 36 programs.[3] Twenty-two programs experienced procurement cost increases due to added quantities. The Littoral Combat Ship reported its total planned procurement for the first time in 2010 and accounts for most of this increase.[4] Fourteen programs experienced procurement cost decreases due to reductions in quantities. The Expeditionary Fighting Vehicle and Medium Extended Air Defense System, which had their production quantities reduced significantly after they were cancelled, account for most of the decrease. The remaining $31.1 billion in procurement cost growth cannot be attributed to quantity changes and is indicative of production problems and inefficiencies or flawed initial cost estimates. For example, the cost to procure the Joint Strike Fighter rose by almost $35 billion because of manufacturing inefficiencies, parts shortages, and quality issues; the number of aircraft procured did not change. Other programs, such as the Virginia-class submarine and the E-2D Advanced Hawkeye, were able to reduce their expected procurement costs without reducing quantities, by improving production processes or negotiating contracts with terms more favorable to the government. Table 2 shows how procurement costs changed across the DOD portfolio due to changes in planned procurement quantities as well as other factors.

[3]To calculate the portion of procurement cost growth attributable to quantity changes, we compared a program's quantities from the December 2009 SAR with its quantities from the December 2010 SAR. When quantities changed, we multiplied the change by the previous average procurement unit cost, using the December 2009 SAR estimate where available, to determine the expected cost growth or decrease due to these quantity changes. The Joint Tactical Radio System Handheld, Manpack, and Small Form Fit changed the mix as well as the quantity of radios procured but this change to radio type is not accounted for in our calculations. The Gray Eagle unmanned aircraft program changed how it calculates quantities for the 2010 SAR. We based our calculation on the change in procurement cost due to quantity for that program on the number of aircraft procured to account for this. See app. I for additional information on our scope and methodology.

[4]The Littoral Combat Ship program was initiated in May 2004 with an acquisition program baseline that included 2 procurement-funded ships. The program did not report its total planned procurement quantity of 53 ships until the December 2010 SAR.

2148 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 2: Change in Procurement Cost Due to Quantity Changes and Other Factors

Fiscal year 2012 dollars in billions

	Number of programs	Actual cost change	Estimated cost change directly attributable to quantity changes	Estimated cost change not directly attributable to quantity changes
Programs with quantity increases	22	$53.6	$63.0	-$9.3
Programs with quantity decreases	14	-28.1	-33.4	5.2
Programs with no change in quantity	59	35.2	0	35.2
Total	**95[a]**	**$60.6**	**$29.6**	**$31.1**

Source: GAO analysis of DOD data.

Note: Figures may not add due to rounding.

[a]The analysis does not include BMDS.

- **Many of the programs with the highest amounts of research and development cost growth in the last year are in production and are utilizing concurrent development and production strategies or funding modernization or upgrade efforts.** Over the past year, the research and development cost associated with the 2011 portfolio has risen 4 percent, or roughly $14 billion, and programs in production account for the overwhelming majority of this growth. This runs counter to what one might expect, namely that programs in production are beyond the point of development cost increases. Table 3 lists examples of these programs and the reasons they cited for their research and development cost growth in the past year.

2149 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 3: Examples of Programs with Significant Research and Development Cost Growth in the Past Year

Program	Growth in last year (dollars in millions)	Reason for growth	Start of production
Joint Strike Fighter	$3,922	Additional funding to reduce risk	2007
Space Based Infrared System High Program	785	Additional funding needed to meet requirements	2001
F-22 Raptor	780	Additional funding for modernization	2001
P-8A Poseidon	742	Additional funding for new increment of capability, correction of deficiencies, and updated estimates	2010
Virginia-class Submarine	727	Additional funding for enhancements, cost reduction initiatives, and testing	1997
Global Hawk	722	Additional funding for the inclusion of new capabilities and testing	2001
DDG 51 Destroyer	656	Additional funding for the inclusion of new capabilities	1985
Trident II Missile	624	Additional funding for modernization and replacement	1987
Apache Block IIIA Remanufacture	506	Additional funding for software development	2010

Source: GAO analysis of DOD data.

Several of these programs, including the Joint Strike Fighter, Space Based Infrared System High, and Apache Block IIIA Remanufacture, have concurrent development and production strategies, which increases manufacturing risk and can result in increased cost and schedule if problems are discovered late in design or production. Other programs, such as the F-22 Raptor, Virginia-class submarine, DDG 51 Destroyer, and Trident II Missile, have begun efforts to add capability to or modernize the system within the existing program. The P-8A Poseidon and Global Hawk have done both. According to DOD's primary acquisition policy—Department of Defense Instruction 5000.02—upgrades, improvements, and similar efforts that provide a significant increase in operational capability and meet the major defense acquisition program threshold should be managed as

2150 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

separate increments.[5] None of the efforts in these six programs were being managed as separate increments.

- **The cost of the portfolio is driven by the 10 highest-cost programs, which account for 55 percent of the total.** DOD's portfolio of major defense acquisition programs is unbalanced. As shown in table 4, the 10 highest-cost programs account for 55 percent, or roughly $868 billion, of the 2011 portfolio's $1.58 trillion total acquisition cost. These programs are also driving overall portfolio outcomes and account for over $53 billion, or about 72 percent, of the total cost growth for the portfolio in the past year. All 10 of these programs are currently in production and all but three—the Joint Strike Fighter, the CVN 78 Class, and the P-8A Poseidon—have attained initial operational capability.

Table 4: Ten Highest-Cost Acquisition Programs in 2011 Portfolio

Fiscal year 2012 dollars in billions

Program	Total acquisition cost	Percent of 2011 portfolio cost
Joint Strike Fighter	$327	21
DDG 51 Destroyer	102	6
Virginia-class Submarine	84	5
F-22 Raptor	79	5
F/A-18E/F Super Hornet	58	4
V-22 Osprey	57	4
Trident II Missile	53	3
Joint Mine Resistant Ambush Protected Vehicle	42	3
CVN 78 Class	34	2
P-8A Poseidon	33	2
Total	**$868**	**55**

Source: GAO analysis of DOD data.

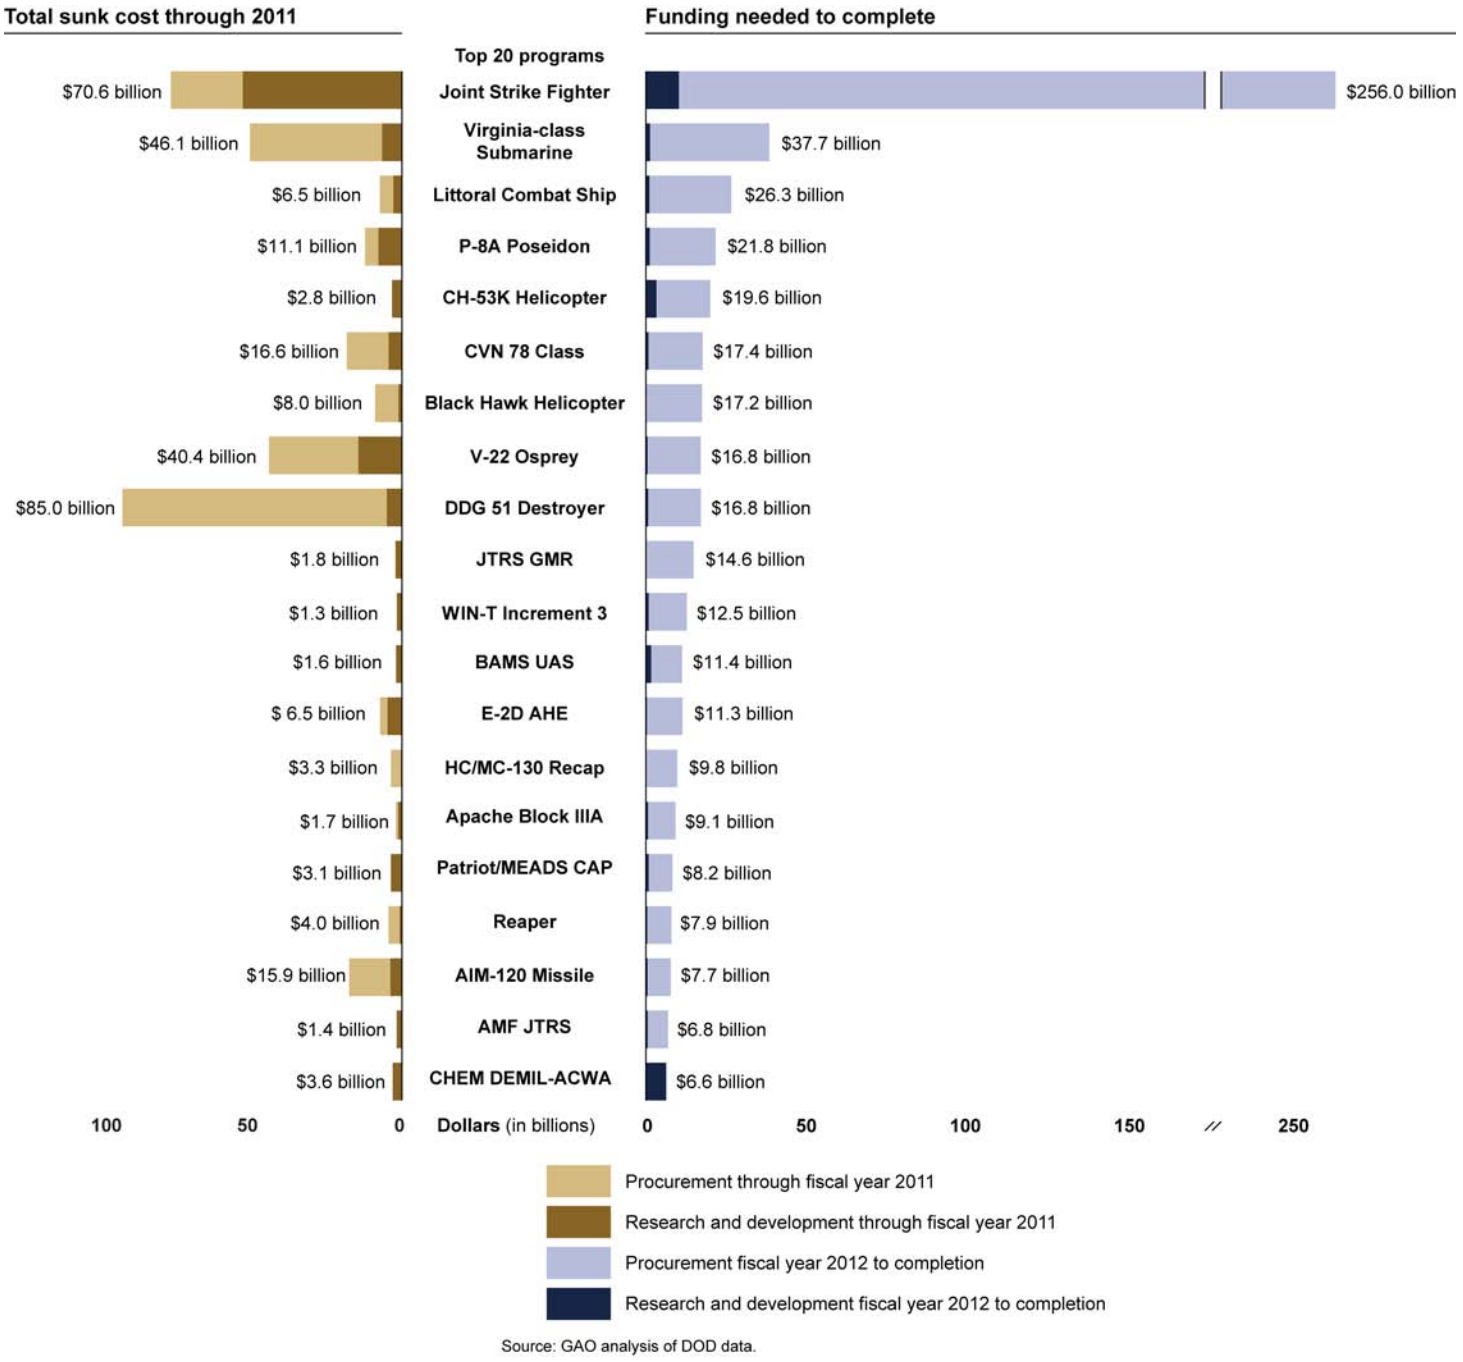
2151 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- **The Joint Strike Fighter is driving much of DOD's poor portfolio performance and it will continue to drive outcomes for the foreseeable future.** Among the 96 programs in DOD's 2011 portfolio, the Joint Strike Fighter is the costliest, the poorest performer in terms of cost growth, and the program with the largest remaining funding needs. The Joint Strike Fighter accounts for 21 percent, or nearly $327 billion, of the planned total acquisition cost of the portfolio. It is also responsible for the most significant research and development, procurement, and total acquisition cost growth in the past year, as shown in figure 1. This growth took place without any change in procurement quantities by the program.

Figure 1: Joint Strike Fighter as a Portion of 2011 Portfolio Cost Growth

Source: GAO analysis of DOD data.



- **Most of the remaining funding for the 2011 portfolio is for procurement.** Over 91 percent of the almost $705 billion needed to complete the programs in the 2011 portfolio consists of procurement funding; therefore, any future funding cuts to these programs will likely result in quantity reductions. The Joint Strike Fighter program alone is expected to account for 38 percent—or almost $246 billion—of the future procurement funding needed. This amount is enough to fund the remaining procurement costs of the next 15 largest programs. Figure 2

2152 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

shows the funding spent and still needed for the 20 programs with the highest remaining funding needs.

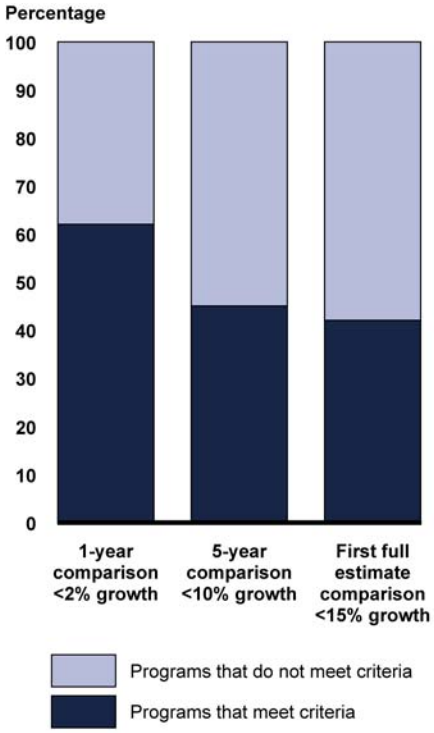
Figure 2: Twenty Costliest Acquisition Programs by Funding Needed to Complete

Source: GAO analysis of DOD data.

2154 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Note: BMDS is excluded from this analysis. JTRS GMR is the Joint Tactical Radio System Ground Mobile Radios; this program was terminated during the course of our review. WIN-T Increment 3 is the third increment of the Warfighter Information Network-Tactical program. BAMS UAS is the Broad Area Maritime Surveillance Unmanned Aircraft System. E-2D AHE is the Advanced Hawkeye. HC/MC-130 Recap is the recapitalization program for the HC/MC-130 aircraft. Patriot/MEADS CAP is the Patriot/Medium Extended Air Defense System Combined Aggregate Program. AMF JTRS is the Airborne and Maritime/Fixed Station Joint Tactical Radio System. CHEM-DEMIL ACWA is Chemical Demilitarization-Assembled Chemical Weapons Alternatives.

- **Buying power, as measured by program acquisition unit cost, has decreased for over 60 percent of programs over the past year.** Of the 96 programs or components in DOD's portfolio that reported program acquisition unit cost data, 61 are planning to deliver capabilities at higher unit costs than estimated a year ago while 35 are planning to deliver capabilities at or below the same estimates.[6] Unit costs are sensitive to how many are being bought. If quantities are decreased, unit costs would be expected to go up and vice versa. However, only 11 of the 61 programs with unit-cost increases in the past year decreased quantities in the past year, indicating that unit-cost growth in the other 50 cases was due to actual research and development or procurement cost growth—not changes in quantities. We did not examine whether these programs delivered a higher or lower level of performance than initially planned.



- **Less than half of the programs in the 2011 portfolio met cost-growth targets used to measure DOD's progress on addressing GAO's weapon system acquisition high-risk area.** In December 2008, DOD, OMB, and GAO discussed a set of cost growth metrics and goals to evaluate DOD's progress on improving program performance for purposes of our high-risk report. These metrics were designed to capture total cost-growth performance over 1-year and 5-year periods as well as from the original program estimate on a percentage basis as opposed to dollar amount to control for the disparity in the amount of funding between programs. As shown in figure 3, 40 percent of major defense acquisition programs did not meet the criteria for less than 2

[6]Program acquisition unit cost is the total cost for development, procurement, acquisition operation and maintenance, and system-specific military construction for the acquisition program divided by the number of items to be produced. DOD's 2011 portfolio includes 96 programs with SARs; however, DOD's SAR summary tables break down several of these programs into smaller elements. We did not include BMDS or the National Polar-orbiting Operational Environmental Satellite System because comparable cost and quantity data were not available, or the Expeditionary Fighting Vehicle and Patriot/Medium Extended Air Defense System Combined Aggregate Program Fire Unit, because these programs were cancelled.

2155 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

percent growth in total acquisition cost over the past year, and over half did not meet the less than 10 percent metric for growth over a 5-year period and the less than 15 percent metric from their first full estimate. When measured against the same criteria for growth using program acquisition unit cost or average procurement unit cost, the percent of programs that do not meet the criteria remain roughly the same.

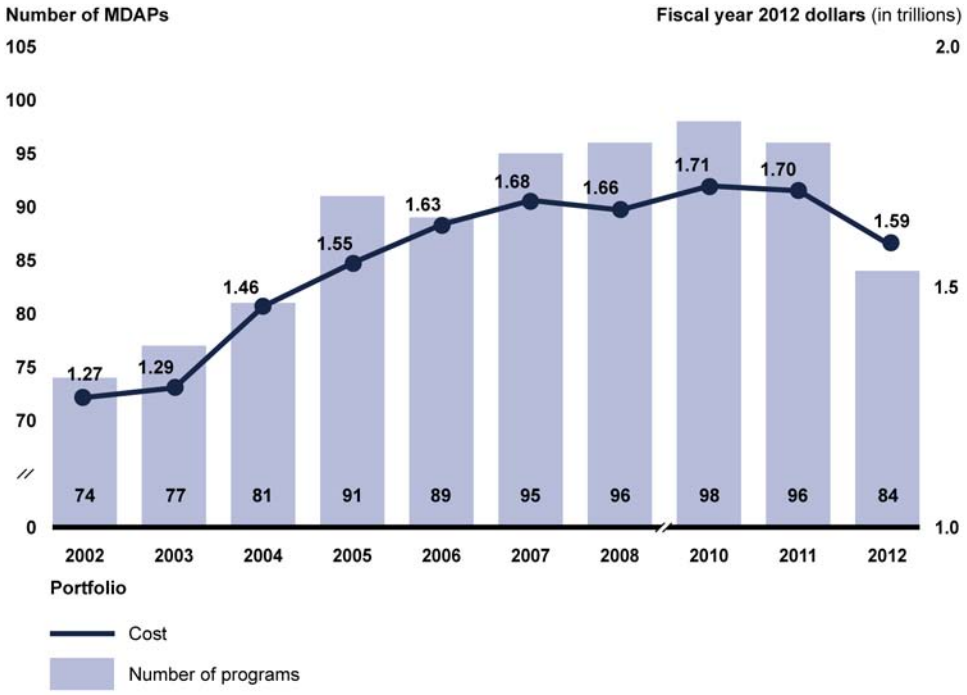
Figure 3: Programs Meeting High-Risk Cost Metrics

Source: GAO analysis of DOD data.

Notes: The number of programs represents those in the 2011 portfolio—those with December 2010 SARs—which break down several programs into smaller elements for reporting purposes. One program, Airborne Signals Intelligence Payload (ASIP), was not included in the 5-year comparisons because data were not available to make that comparison. BMDS was not included in this analysis.

- **The number of programs in DOD's portfolio decreased in fiscal year 2011 and, looking forward, is expected to decrease again in the next fiscal year to its lowest level since 2004.** DOD's portfolio for 2011 contains 96 major defense acquisition programs, a net decrease of 2 since last year. Six programs left the portfolio and four programs

2156 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING



entered.[7] The six programs that left the portfolio cost an estimated $108 billion to develop and produce, and the four new entries are expected to cost $29 billion. Based on DOD data on programs that will enter and exit the portfolio in fiscal year 2011, we project that the number of programs and DOD's total planned investment in them will decrease again in the next fiscal year.[8] As shown in figure 4, the expected decrease would reduce the number of programs to its lowest level since 2004.

[7]The six programs that exited the portfolio were Bradley armored fighting vehicle upgrade, C-17A aircraft, CVN 68 aircraft carrier, EA-6B Improved Capability III aircraft, Minuteman III Propulsion Replacement Program, and the MQ-1B Predator unmanned aircraft. The four that entered were Apache Block IIIB New Build helicopter, HC/MC-130 Recapitalization program, KC-130J aircraft, and Small Diameter Bomb Increment II.

[8]The programs exiting the portfolio in 2012 will do so because of cancellation or delivery of 90 percent of end items. Programs include: Airborne Signals Intelligence Payload, Advanced Threat Infrared Countermeasure/Common Missile Warning System, B-2 Radar Modernization Program, C-5 Avionics Modernization Program, Expeditionary Fighting Vehicle, F-22 Raptor, Force XXI Battle Command Brigade and Below, Increment 1 Early-Infantry Brigade Combat Team, Joint Mine Resistant Ambush Protected vehicle, Large Aircraft Infrared Countermeasures, Longbow Apache, Space Based Space Surveillance Block 10, and the Lewis and Clark-class Dry Cargo/Ammunition ship (T-AKE). The one program that is currently scheduled to become a major defense acquisition program and begin annual selected acquisition reporting in fiscal year 2012 is the KC-46 Tanker Modernization Program.

2157 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 4: Number of Programs in DOD Portfolio over the Past 10 Years

Source: GAO analysis of DOD data.

Note: The 2009 portfolio is excluded because there were no annual SARs released for 2008. The 2012 portfolio is projected from DOD data.

It is not clear whether this reduction in the number of programs in the portfolio is the result of DOD's recognition of the increasing constraints on the defense budget and the beginning of a longer-term trend or whether it is a 1-year anomaly resulting from a number of large and capital-intense programs, such as F-22 and the Joint Mine Resistant Ambush Protected vehicle, leaving the portfolio. Regardless, if the cost growth of the programs remaining in the portfolio can be controlled, the end result would be a better balance between the number of programs and DOD's available resources.

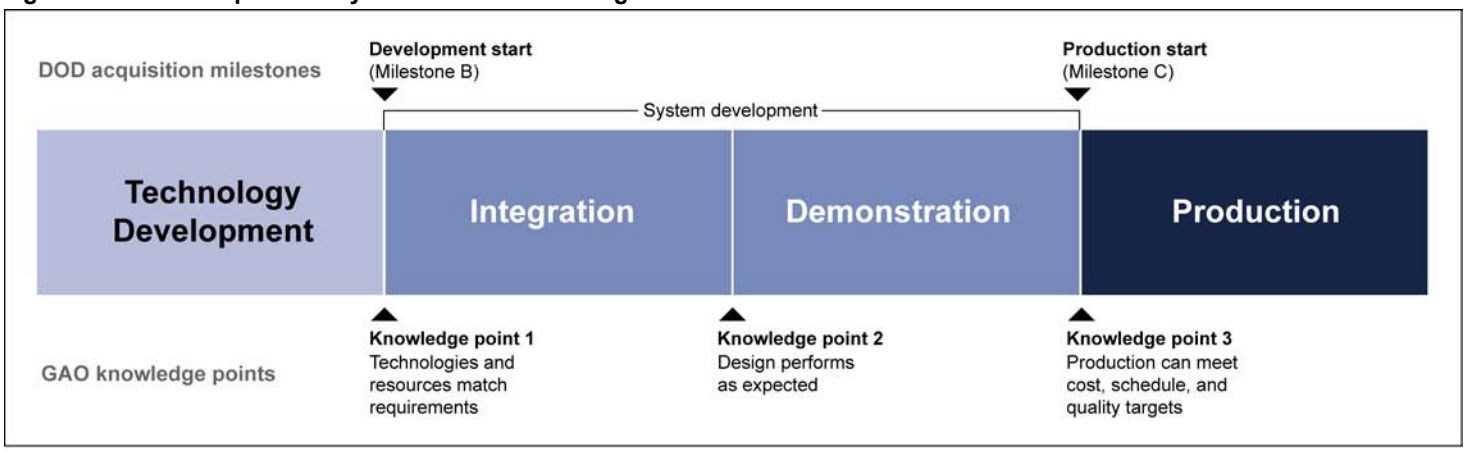
Observations from Our Assessment of Knowledge Attained by Programs That Have Not Yet Reached Full-Rate Production



Positive acquisition outcomes require the use of a knowledge-based approach to product development that demonstrates high levels of knowledge before significant commitments are made. In essence, knowledge supplants risk over time. In our past work examining weapon acquisitions and best practices for product development, we have found that leading commercial firms and successful DOD programs pursue an acquisition approach that is anchored in knowledge, whereby high levels of product knowledge are demonstrated by critical points in the acquisition process.[9] On the basis of this work, we have identified three key knowledge points during the acquisition cycle—development start, critical design review, and production start—at which programs need to demonstrate critical levels of knowledge to proceed.[10] Figure 5 aligns the acquisition milestones described in DOD's primary acquisition policy with these knowledge points. In this report, we refer to DOD's engineering and manufacturing development phase as system development. Production start typically refers to a program's entry into low-rate initial production.

[9]GAO, *Best Practices: Better Management of Technology Development Can Improve Weapon System Outcomes*, GAO/NSIAD-99-162 (Washington, D.C.: July 30, 1999); GAO, *Best Practices: Better Matching of Needs and Resources Will Lead to Better Weapon System Outcomes*, GAO-01-288 (Washington, D.C.: Mar. 8, 2001); GAO, *Best Practices: Capturing Design and Manufacturing Knowledge Early Improves Acquisition Outcomes*, GAO-02-701 (Washington, D.C.: July 15, 2002); GAO, *Defense Acquisitions: A Knowledge-Based Funding Approach Could Improve Major Weapon System Program Outcomes*, GAO-08-619 (Washington, D.C.: July 2, 2008); GAO, *Best Practices: High Levels of Knowledge at Key Points Differentiate Commercial Shipbuilding from Navy Shipbuilding*, GAO-09-322 (Washington, D.C.: May 13, 2009); GAO, *Best Practices: DOD Can Achieve Better Outcomes by Standardizing the Way Manufacturing Risks Are Managed*, GAO-10-439 (Washington, D.C: Apr. 22, 2010).

[10]For shipbuilding programs, we have identified two key knowledge points during the acquisition cycle—detail design contract award and fabrication start.

2159 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 5: DOD's Acquisition Cycle and GAO Knowledge Points

Source: GAO.

The building of knowledge consists of information that should be gathered at these three critical points over the course of a program:

Knowledge point 1: Resources and requirements match. Achieving a high level of technology maturity by the start of system development is one of several important indicators of whether this match has been made. This means that the technologies needed to meet essential product requirements have been demonstrated to work in their intended environment. In addition, the developer should complete a series of systems engineering reviews culminating in a preliminary design of the product that shows the design is feasible. Constraining the development phase of a program to 5 to 6 years is also recommended because it aligns with DOD's budget planning process and increases funding predictability. For shipbuilding programs, critical technologies should be matured into actual system prototypes and successfully demonstrated in a realistic environment before a contract is awarded for detail design of a new ship.

Knowledge point 2: Product design is stable. This point occurs when a program determines that a product's design will meet customer requirements, as well as cost, schedule, and reliability targets. A best practice is to achieve design stability at the system-level critical design review, usually held midway through system development. Completion of at least 90 percent of engineering drawings at this point provides tangible evidence that the product's design is stable, and a prototype demonstration shows that the design is capable of meeting performance

2160 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

requirements. Shipbuilding programs should demonstrate design stability by completing 100 percent of the basic and functional drawings as well as the three-dimensional product model, when employed, by the start of construction for a new ship. Programs can also improve the stability of their design by conducting reliability growth testing and completing failure modes and effects analyses so fixes can be incorporated before production begins. At this point, programs should also begin preparing for production by identifying manufacturing risks, key product characteristics, and critical manufacturing processes.

Knowledge point 3: Manufacturing processes are mature. This point is achieved when it has been demonstrated that the developer can manufacture the product within cost, schedule, and quality targets. A best practice is to ensure that all critical manufacturing processes are in statistical control—that is, they are repeatable, sustainable, and capable of consistently producing parts within the product's quality tolerances and standards—at the start of production. Demonstrating critical processes on a pilot production line is an important initial step in this effort. In addition, production and postproduction costs are minimized when a fully integrated, capable prototype is demonstrated to show that the system will work as intended in a reliable manner before committing to production. We did not assess shipbuilding programs for this knowledge point due to differences in the production processes used to build ships.

A knowledge-based acquisition approach is a cumulative process in which certain knowledge is acquired by key decision points before proceeding. Demonstrating technology maturity is a prerequisite for moving forward into system development, during which the focus should be on design and integration. A stable and mature design is likewise a prerequisite for moving forward into production where the focus should be on efficient manufacturing. Additional details about key practices at each of the knowledge points can be found in appendix IV.

Overall, we assessed the knowledge attained by key junctures in the acquisition process for 37 individual weapon programs, which are mostly in development or early production.[11] In particular, we focused on the eight

[11]Not all programs provided information for every knowledge point or had reached all of the knowledge points—development start, design review, and production start. Because knowledge points and best practices differ for shipbuilding programs, we exclude the five shipbuilding programs in our assessment from some of our analysis.

2161 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

programs from this group that progressed through key acquisition points in 2011—one program began system development, four programs held critical design reviews, and three programs began production. Only one of these eight programs—Excalibur Increment Ib—implemented all of the applicable knowledge-based acquisition practices at these points; and overall, most of the 37 programs we assessed are not fully adhering to a knowledge-based approach, putting them at higher risk of cost growth and schedule delays. Our analysis of the eight programs that went through key acquisition points in 2011 allows us to make three observations.

Knowledge Point Observations

1. The one program that began system development in 2011 did so with all of its critical technologies nearing maturity, but without demonstrating them in a realistic environment.

2. Three of four programs that held critical design reviews in 2011 did so with stable designs, but only one tested an integrated prototype to demonstrate that the design was capable of meeting performance requirements.

3. One of the three programs that held a production decision in 2011 reported that its critical manufacturing processes were in control; one of the three programs demonstrated their production processes on a pilot production line; and two of the three programs tested production-representative prototypes to demonstrate reliable performance.

Additional detail about these observations follows.

- **The only program in our assessment that began development in 2011 did so with all of its critical technologies nearing maturity, but without demonstrating them in a realistic environment.** The KC-46 tanker began development with all its critical technologies at least nearing maturity—that is, demonstrated in a relevant environment—in accordance with DOD policy and statutory requirements.[12] Models of these technologies were demonstrated on other aircraft or in simulations. However, knowledge-based acquisition

[12]According to DOD policy, in order to be considered mature enough to use in product development, technology shall have been demonstrated in a relevant environment or, preferably, in an operational environment. Department of Defense Instruction 5000.02, *Operation of the Defense Acquisition System*, enc. 2, para. 5.d(4). In addition, a major defense acquisition program may not receive milestone B approval (development start) until the milestone decision authority certifies that the technology in the program has been demonstrated in a relevant environment. 10 U.S.C. § 2366b(a)(3)(D).

2162 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

practices recommend and DOD policy prefers that programs fully mature technologies and demonstrate them in a realistic or operational environment prior to entering system development, to gain additional knowledge about the technologies' form, fit, and function as well as the effect of the intended environment on those technologies.[13] Our analysis of the 37 programs in our assessment that provided technology data shows that 20 programs reported having all critical technologies at least nearing maturity prior to entering system development, with only 4 of those fully maturing their technologies. Of the five shipbuilding programs we assessed, only one had all its critical technologies fully mature before awarding its detailed design contract, the point at which technology maturity should be achieved.

Key acquisition practices also recommend, and statute requires, that programs hold systems engineering events, such as a preliminary design review, before development start to ensure that requirements are defined and feasible and that the proposed design can meet those requirements within cost, schedule, and other system constraints.[14] The KC-46 program received a waiver to enter development without conducting a preliminary design review, and plans to hold it in March 2012, about 13 months after development start. Overall, 29 of the 37 programs we assessed failed to hold preliminary design reviews prior to the start of development or the award of their detailed design contracts. Our analysis shows that these programs experienced, on average, more research and development cost growth and total acquisition cost growth than programs that held the review before these points.

Knowledge-based acquisition practices also recommend limiting the time a program or an increment of a program spends in development to

[13]Demonstration in a relevant environment is Technology Readiness Level (TRL) 6. Demonstration in a realistic environment is TRL 7. See app. V for a detailed description of TRLs.

[14]GAO, *Defense Acquisitions: Assessments of Selected Weapon Programs*, GAO-09-326SP (Mar. 30, 2009). A major defense acquisition program may not receive milestone B approval until the program has held a preliminary design review and the milestone decision authority has conducted a formal postpreliminary design review assessment and certified on the basis of such assessment that the program demonstrates a high likelihood of accomplishing its intended mission. 10 U.S.C. § 2366b(a)(2).

2163 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

5 or 6 years, and the KC-46 program plans to do so.[15] Constraining development time in this manner increases the predictability of funding needs as well as the likelihood of program success. Of the 32 programs whose development cycles we assessed, 21 currently plan to constrain their development time to 6 years or less. We did not assess shipbuilding programs against this metric as their development cycles do not align in a manner consistent with other programs. Figure 6 summarizes the KC-46 program's implementation of knowledge-based acquisition practices related to development start.

- **Three of four programs in our assessment that held a critical design review in 2011 demonstrated that their designs were stable, but only one showed that its design would perform as intended.** Knowing a product's design is stable before system demonstration reduces the risk of costly design changes occurring during manufacturing of production-representative prototypes—when investments in acquisition become more significant. For shipbuilding

[15]Additionally, DOD policy provides that a condition for exiting the technology development phase is that a system or increment can be developed for production within a short time frame, defined as normally less than 5 years for weapon systems. Department of Defense Instruction 5000.02, *Operation of the Defense Acquisition System*, enc. 2, para. 5.d(7).

2164 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

programs, starting fabrication of the lead ship with a stable design can minimize out-of-sequence work and rework, as Navy lead ships often become the platform upon which planned capabilities are eventually proven. Three of the four programs that completed a critical design review in 2011 stabilized their designs by releasing at least 90 percent of their total expected design drawings. Overall, 8 of the 37 programs we assessed released over 90 percent of their total expected design drawings before holding a critical design review or, for ships, demonstrated stable designs by completing 100 percent of their three-dimensional design models prior to the start of fabrication.

We have previously reported that early system prototypes are useful to demonstrate that the design will work as anticipated and can be built within cost and schedule. Only one of the four programs that held its critical design review in 2011—the Excalibur Increment Ib—demonstrated that its design was capable of meeting performance requirements by testing an integrated prototype before the design review. On average, the other three programs plan to test an integrated prototype 15 months after the critical design review, similar to the 13-month average we reported in last year's assessment. Overall, only 5 of the 32 programs we assessed for this purpose tested a system-level integrated prototype by the time of their critical design review. We did not assess shipbuilding programs against this metric as testing a system-level prototype in these programs may not be practical.

Reliability growth testing provides visibility over how reliability is improving and uncovers design problems so fixes can be incorporated before production begins. Three of the four programs that held a critical design review in 2011 established a reliability growth curve. Overall, 18 of the 37 programs we assessed had a reliability growth curve by the same point. Figure 7 shows how the four programs that held critical design reviews in 2011 performed against these and other knowledge-based practices.

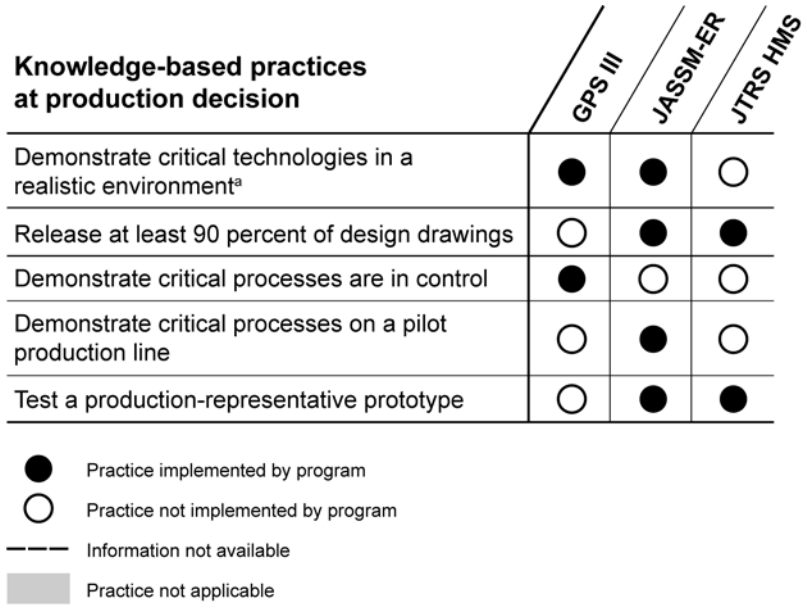
- **One of the three programs that held a production decision in 2011 had its critical manufacturing processes in control; one of the three demonstrated production processes on a pilot production line; and two of the three tested production-representative prototypes.** Capturing critical manufacturing knowledge before entering production helps ensure that a weapon system will work as intended and can be manufactured efficiently to meet cost, schedule, and quality targets. For example, bringing processes under statistical control reduces variations in parts manufacturing, thus reducing the potential for defects, and is generally less costly than performing extensive inspection after a product is built. One of the three programs that held a production decision in 2011—Global Positioning System

2166 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

III—provided data that demonstrated its critical manufacturing processes were in control at production start.[16] Overall, 4 of the 32 programs in our production assessment provided data demonstrating their critical processes were in control. It is also DOD policy for manufacturing processes to be effectively demonstrated in a pilot-line environment before entering production.[17] One of the three programs that held a production decision in 2011—Joint Air-to-Surface Standoff Missile–Extended Range (JASSM-ER)—demonstrated its critical processes on a pilot production line. Overall, 26 of 32 programs reported that they have or planned to demonstrate their critical processes on a pilot line before production start.

Production and postproduction costs are also minimized when a fully integrated, capable prototype is demonstrated to show that the system will work as intended in a reliable manner. Since 2008, DOD policy has also required that a system be demonstrated in its intended environment using a production-representative article before entering production, which has led to an increase in the number and percentage of programs doing so.[18] Two of three programs that held production decisions in 2011 tested production-representative prototypes before committing to production. Overall, according to our analysis of survey results, one of the six programs that held their production decisions prior to 2009 tested production-representative prototypes prior to production start; and 15 of the 24 programs that have held or will hold production decisions after 2009 have tested or plan to test a production-representative prototype before those decisions. Figure 8 shows how the three programs that held production decisions in 2011 performed against relevant knowledge-based practices.



[16]In addition to using Process Capability Index data to determine whether critical processes are in control, we used data from manufacturing readiness level assessments of the process capability and control sub-thread to assess production process maturity. For more information on our methodology see app. I.

Observations about DOD's Implementation of Acquisition Policy Reforms

In the past few years, a number of acquisition reform initiatives have been introduced both through legislation and through efforts undertaken by DOD; specifically the Weapon Systems Acquisition Reform Act of 2009, the reissuance of DOD Instruction 5000.02, and the Under Secretary of Defense for Acquisition, Technology and Logistics' "Better Buying Power" memorandum.[19] We assessed the implementation of four sections of the Weapon Systems Acquisition Reform Act of 2009, including requirements for major defense acquisition programs to: (1) conduct preliminary design

[19]Pub. L. No. 111-23. Department of Defense Instruction 5000.02, *Operation of the Defense Acquisition System* (Dec. 8, 2008); Office of the Under Secretary of Defense, Acquisition, Technology and Logistics Memorandum: "Better Buying Power: Guidance for Obtaining Greater Efficiency and Productivity in Defense Spending" (Sept. 14, 2010).

2168 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

reviews before development start; (2) demonstrate capabilities using competitive prototypes; (3) ensure that appropriate trade-offs among cost, schedule, and performance objectives are considered before development start; and (4) include measures to ensure competition or the option of competition throughout the programs' life cycle in their acquisition strategies. We also assessed a new requirement from the 2008 revision to DOD Instruction 5000.02 for a materiel development decision prior to a program's entry into the acquisition process and two initiatives from DOD's September 2010 better buying power memorandum focusing on affordability and "should cost" targets. Many of these reforms and others depend on increased investments of time and resources at the beginning of the acquisition process and encourage an awareness of cost performance throughout a program's life cycle. Increased funding of technology development can have beneficial effects for acquisition programs if the funds are spent on activities appropriate for that phase, such as prototype demonstrations and systems engineering analysis.

Our analysis of 16 future and 37 current major defense acquisition programs allows us to make three observations concerning DOD's progress in implementing these reforms.

Acquisition Reform Observations

1. Almost all of the future major defense acquisition programs we assessed have implemented or plan to implement acquisition reforms from the Weapon Systems Acquisition Reform Act of 2009; current programs have a mixed record in regards to implementing certification requirements from the act, such as considering appropriate trade-offs among cost, schedule, and performance objectives.
2. Some future programs have not implemented the new DOD policy requirement to hold a materiel development decision, and many future and current programs are still working to implement new initiatives, such as developing affordability targets and conducting "should cost" analysis.
3. The 16 future major defense acquisition programs we assessed are investing more funds before entering system development or production than current major defense acquisition programs, which should reduce their technical risk.

Additional information about these observations follows.

- **Almost all future programs have implemented, or plan to implement, most of the legislative reforms we examined. Current programs have waived several of the newest certification requirements.** The Weapon Systems Acquisition Reform Act of 2009

2169 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

introduced a requirement for a preliminary design review to be held for all major defense acquisition programs before the start of system development.[20] Eleven of the 16 future major defense acquisition programs in our assessment intend to conduct such a review in accordance with the act. Four of the remaining programs have not yet established a date for their preliminary design reviews; the fifth program is not required to hold a preliminary design review because it expects to enter the acquisition cycle at production start.

The Weapon Systems Acquisition Reform Act of 2009 also requires the acquisition strategy for major defense acquisition programs to provide for use of competitive prototypes before a program enters system development, which can provide a program with an opportunity to reduce technical risk, refine requirements, validate designs and cost estimates, and evaluate manufacturing processes. According to the results of our survey, 13 of the 16 future programs in our assessment intend to develop prototypes of the proposed weapon system or key subsystems before development start. Three programs do not intend to use prototyping and two of those programs intend to seek a waiver from the prototyping requirement, as provided by the act. The program that does not intend to seek the waiver—the Common Vertical Lift Support Platform—is proceeding directly to production and the competitive prototyping requirement is not applicable.

A requirement for major defense acquisition programs to have acquisition strategies that ensure competition or the option of competition throughout the acquisition life cycle was also included in the Weapon Systems Acquisition Reform Act of 2009.[21] Use of competition throughout a program's life cycle can help to reduce program costs. Measures to ensure competition or the option of competition may include developing competitive prototypes, using modular open architectures to enable competition for upgrades, and holding periodic system or program reviews to address long-term competitive effects of program decisions. Eleven of the 16 future programs in our assessment intend to use these measures or options after development start. Figure 9 summarizes the progress in implementing selected acquisition reforms for future programs.

The Weapon Systems Acquisition Reform Act of 2009 also required, as part of a mandatory program certification prior to development start, an analysis that appropriate trade-offs among cost, schedule, and performance objectives have been made to ensure the program is affordable.[22] The mandatory certification also requires that, before development start, a major defense acquisition program hold a

[22]Pub. L. No. 111-23, § 201(f).

2171 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

preliminary design review, have technology demonstrated in a relevant environment, have completed cost and schedule estimates with concurrence of the Director of Cost Assessment and Program Evaluation (CAPE), have funding available to execute the development and production of the program, perform an analysis to consider other alternatives, and have program requirements approved by the Joint Requirements Oversight Council. A waiver may be granted for any one or more provisions of this certification if it is determined that without the waiver the department would be unable to meet critical national security objectives. As shown in table 5, all three programs that received this certification in the past year—the KC-46 tanker, Littoral Combat Ship Seaframe, and DDG 1000 Destroyer—were granted waivers for multiple certification provisions.

Table 5: Certification Waivers Granted for Programs in 2011

Program	Waiver granted
KC-46 tanker	Trade-offs considered Full funding availability Preliminary design review held
Littoral Combat Ship Seaframe	Trade-offs considered Cost and schedule estimates with CAPE concurrence Full funding availability
DDG 1000 Destroyer	Trade-offs considered Full funding availability

Source: GAO analysis of DOD data.

Note: The DDG 1000 Destroyer program was required to be recertified following a Nunn-McCurdy unit-cost breach of the critical threshold. A breach of the critical cost growth threshold occurs when the program's acquisition unit cost or the procurement unit cost increases by at least 25 percent over the current baseline estimate or at least 50 percent over the original baseline estimate. 10 U.S.C. § 2433.

- **Some future programs have not implemented a DOD policy requirement to hold a materiel development decision, and a majority of future and current programs are still working to implement initiatives on developing affordability and "should cost" targets.** In 2008, DOD revised its primary acquisition policy to require a materiel development decision review as the formal entry point into the acquisition process. This review determines the acquisition phase where a program will enter the acquisition management system, and approves the parameters for analyzing the alternatives that might be able to address a defined capability need. Six of the 16 future programs we assessed have held or intend to hold this

2172 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

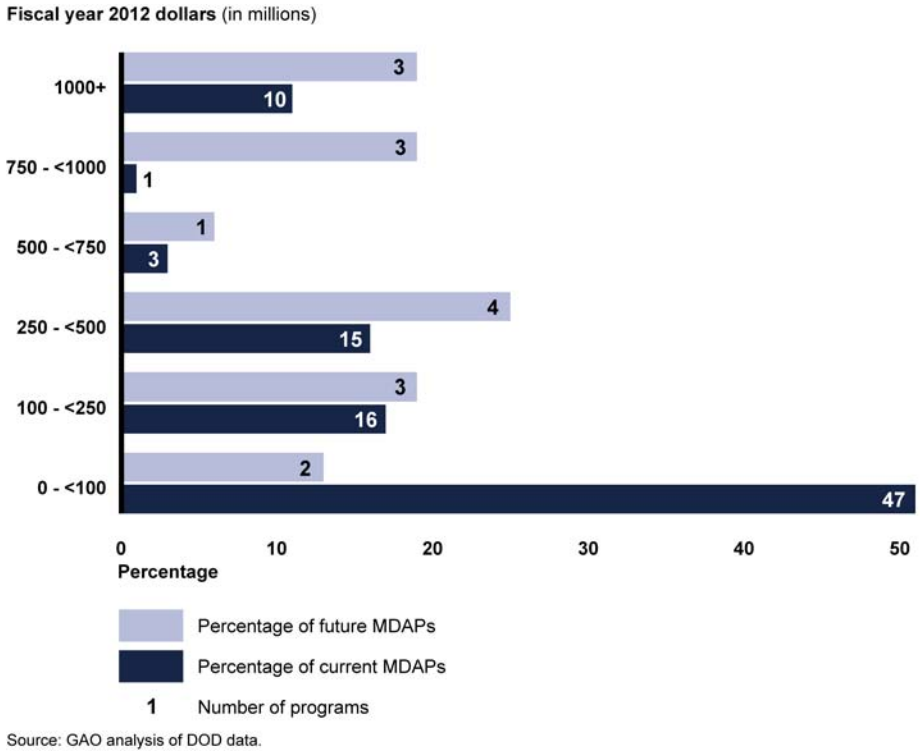
review.[23] Of the 10 future programs that did not hold a materiel development decision review, three—Three Dimensional Expeditionary Long Range Radar, Air and Missile Defense Radar, and Space Fence—began their respective technology development phases after DOD's policy instruction was revised in 2008.[24]

In September 2010, the Under Secretary of Defense for Acquisition, Technology and Logistics issued a memorandum intended to promote greater efficiency and productivity in defense spending. The memorandum emphasizes the need to treat affordability, defined as conducting a program at a cost constrained by the resources that DOD can allocate, as a key requirement akin to speed or power, and mandates establishing an affordability target at program start. According to our analysis of survey responses, 4 of the 16 future and 19 of the 37 current major defense acquisition programs we assessed have established affordability targets. For example, the Navy's planned Ohio-class submarine replacement program established an affordability target at the start of technology development. To assist in meeting this target, the Navy is working to identify areas where costs can be controlled by using existing technologies and aligning the program's production with the Virginia-class submarine. By incorporating these measures, the Navy expects to reduce the estimated cost of each submarine from $5.6 billion to $4.9 billion.

The Under Secretary's initiatives also emphasize the importance of driving cost improvements during contract negotiation and program execution. In accordance with direction provided in the memorandum, each program must conduct a "should cost" analysis justifying each element of the program with the aim of reducing negotiated prices for contracts. According to our analysis of survey responses, 6 of the 16 future and 23 of the 37 current major defense acquisition programs we assessed indicate that they have completed this type of analysis. For

[23]These programs include: B-2 Defensive Management System Modernization, Common Vertical Lift Support Platform, Ground Combat Vehicle, Combat Rescue Helicopter, Ohio-class Replacement, and Ship to Shore Connector.

[24]The programs that do not plan to hold a materiel development decision include: Three Dimensional Expeditionary Long Range Radar, Air and Missile Defense Radar, B-2 Extremely High Frequency SATCOM Capability Increment 2, Enhanced Polar System, Global Positioning System III OCX Ground Control Segment, Joint Air-to-Ground Missile, Joint Light Tactical Vehicle, Littoral Combat Ship Mission Modules, Nett Warrior, and Space Fence.



2173 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

example, the Navy's E-2D Advanced Hawkeye program completed a "should cost" analysis and used the knowledge gained to negotiate a 4.5 percent reduction in its third production contract.

- **The 16 future major defense acquisition programs we assessed intend to invest significantly more funds prior to entering system development or production than current programs.** Many of the recent acquisition reforms mandated by Congress or initiated by DOD increase knowledge prior to the start of system development. These activities help programs ensure that there is a match between requirements and resources before they begin, but they take money. As a result, DOD is beginning to allocate more funding earlier in a program's life cycle, according to our analysis of program spending plans. DOD spent over $450 million, on average, on 92 current major defense acquisition programs that reported cost data for the period prior to entering system development. For the 16 future programs in our analysis, DOD currently plans to spend an average of almost $700 million, or over $11 billion in total, before these programs begin system development or start production and bypass system development. See figure 10 for the amount of funding that future programs plan to spend and current programs spent.

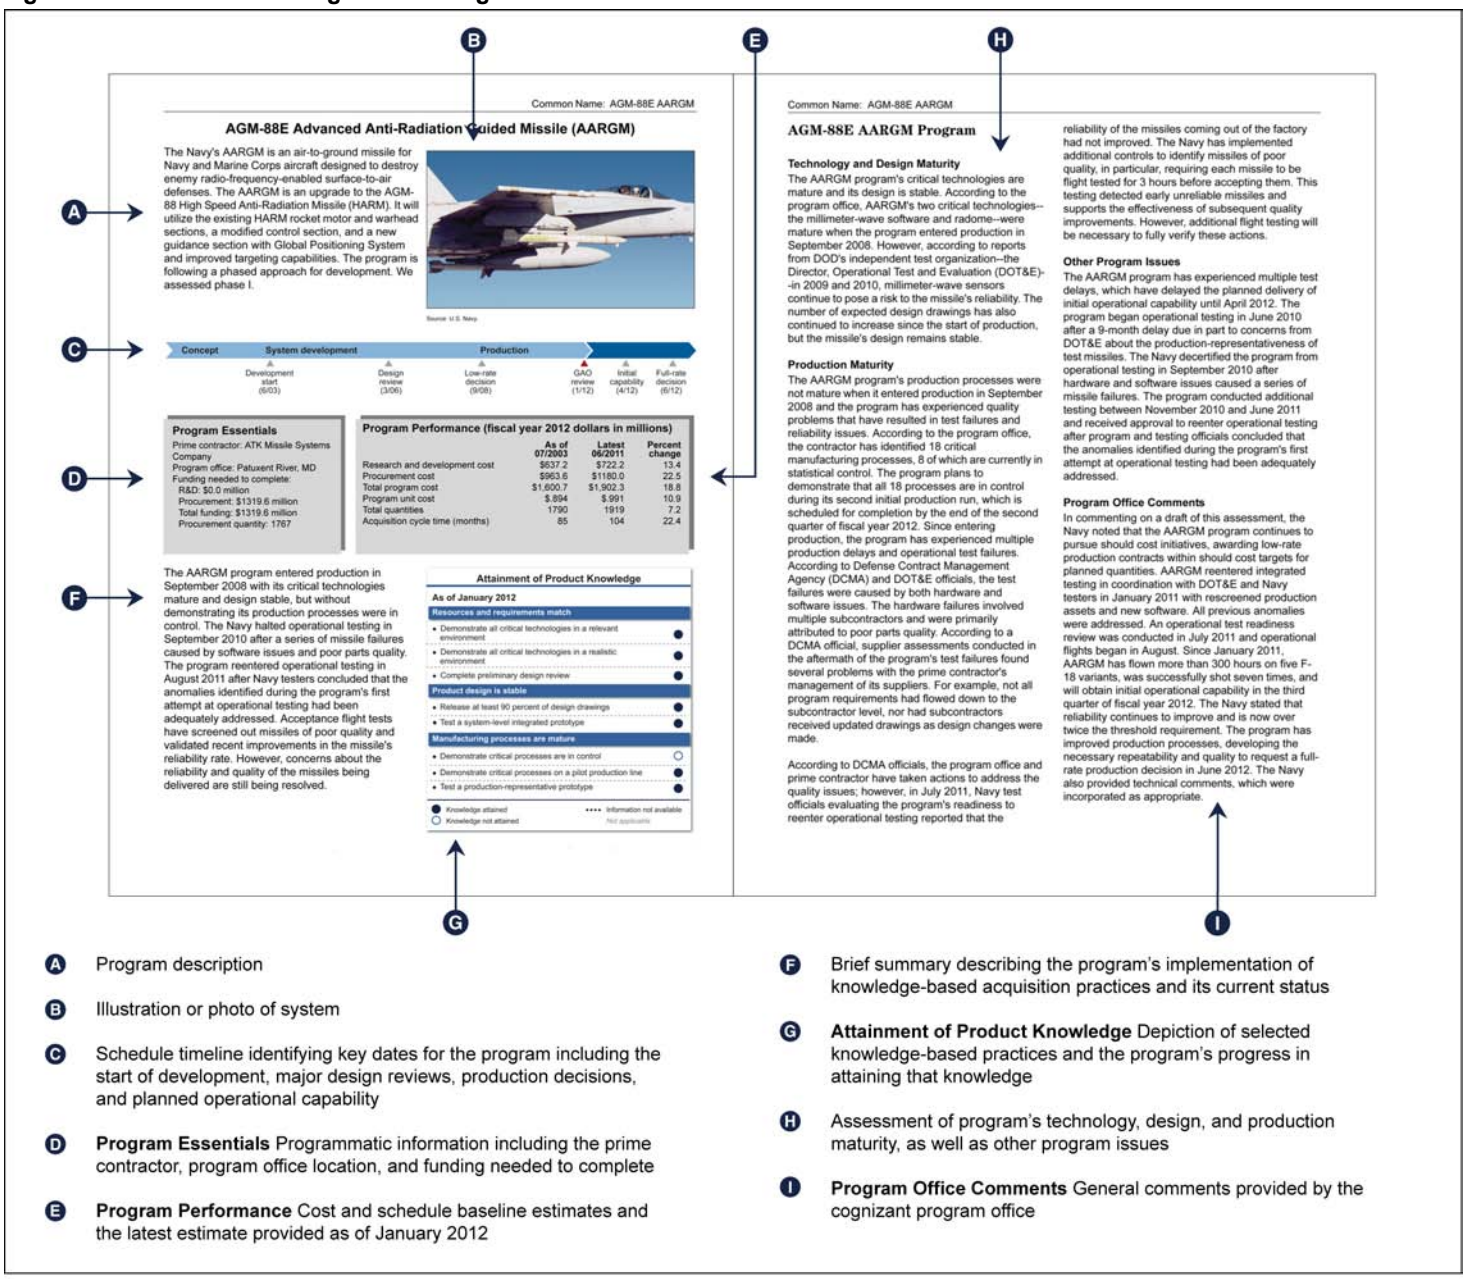
2174 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 10: Funding for Future and Current Programs during Technology Development

Source: GAO analysis of DOD data.

For example, the Navy's Littoral Combat Ship Mission Modules and Ohio-class submarine replacement programs are projected to spend more than $1.2 billion and $2.4 billion respectively in technology development, and the Army's Ground Combat Vehicle expects to spend more than $1.9 billion in technology development. Increased funding of technology development can have beneficial effects for acquisition programs if the funds are spent on activities appropriate for that phase, such as prototype demonstrations and systems engineering analysis.

Assessments of Individual Programs



This section contains assessments of individual weapon programs. Each assessment presents data on the extent to which programs are following a knowledge-based acquisition approach to product development, and other program information. In total, we present information on 68 programs. For 48 programs, we produced two-page assessments discussing the

2175 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

technology, design, and manufacturing knowledge obtained, as well as other program issues. Each two-page assessment also contains a comparison of total acquisition cost from the first full estimate for the program to the current estimate. The first full estimate is generally the cost estimate established at development start; however, for a few programs that did not have such an estimate, we used the estimate at production start instead. For shipbuilding programs, we used their planning estimates if those estimates were available. For programs that began as non–major defense acquisition programs, we used the first full estimate available. Thirty-seven of these 48 two-page assessments are of major defense acquisition programs, most of which are in development or early production; 5 assessments are of elements of MDA's BMDS; and 6 assessments are of programs that were projected to become major defense acquisition programs during or soon after our review. See figure 11 for an illustration of the layout of each two-page assessment. In addition, we produced one-page assessments on the current status of 20 programs, which include 14 future major defense acquisition programs, 2 major defense acquisition programs that are well into production, 1 element of MDA's BMDS, and 3 major defense acquisition programs that were recently terminated.

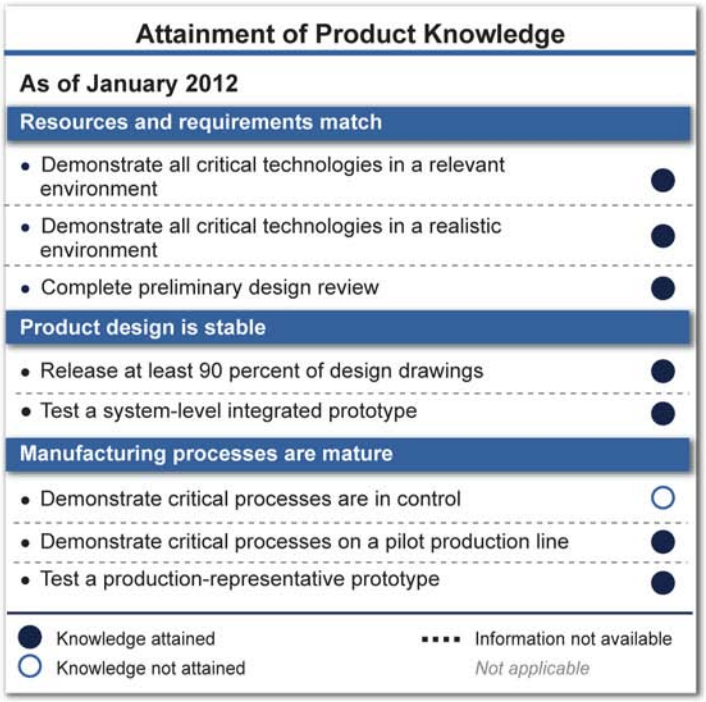
2177 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

How to Read the Knowledge Scorecard for Each Program Assessed

For our two-page assessments, we depict the extent of knowledge gained in a program by the time of our review with a scorecard and narrative summary at the bottom of the first page of each assessment. As illustrated in figure 11 above, the scorecard displays eight key knowledge-based acquisition practices that should be implemented by certain points in the acquisition process. The more knowledge the program has attained by each of these key points, the more likely the weapon system will be delivered within its estimated cost and schedule. A knowledge deficit means the program is proceeding without sufficient knowledge about its technologies, design, or manufacturing processes, and faces unresolved risks that could lead to cost increases and schedule delays.



For each program, we identify a knowledge-based practice that has been implemented with a blue circle. We identify a knowledge-based practice that has not yet been implemented with an open circle. If the program did not provide us with enough information to make a determination, we show this with a dashed line. A knowledge-based practice that is not applicable to the program is grayed out. A knowledge-based practice may not be applicable to a particular program if either the point in the acquisition cycle when the practice should be implemented has not yet been reached, or if the particular practice is not relevant to the program. For programs that have not yet entered system development, we show a projection of knowledge attained for the first three practices. For programs that have entered system development but not yet held a critical design review, we assess actual knowledge attained for these three practices. For programs that have held a critical design review but not yet entered production, we assess knowledge attained for the first five practices. For programs that have entered production, we assess knowledge attained for all eight practices.

We make adjustments to both the key points in the acquisition cycle and the applicable knowledge-based practices for shipbuilding programs. For shipbuilding programs that have not yet awarded a detailed design contract, we show a projection of knowledge attained for the first three practices. For shipbuilding programs that have awarded this contract but not yet started construction, we would assess actual knowledge attained for these three practices. For shipbuilding programs that have started construction, we assess the knowledge attained for the first four practices. We do not assess the remaining four practices for shipbuilding programs. See figure 12 for examples of the knowledge scorecards we use to assess these different types of programs.

AGM-88E Advanced Anti-Radiation Guided Missile (AARGM)

The Navy's AARGM is an air-to-ground missile for Navy and Marine Corps aircraft designed to destroy enemy radio-frequency-enabled surface-to-air defenses. The AARGM is an upgrade to the AGM-88 High Speed Anti-Radiation Missile (HARM). It will utilize the existing HARM rocket motor and warhead sections, a modified control section, and a new guidance section with Global Positioning System and improved targeting capabilities. The program is following a phased approach for development. We assessed phase I.

Source: U.S. Navy.

Program Essentials

Prime contractor: ATK Missile Systems Company
Program office: Patuxent River, MD
Funding needed to complete:
- R&D: $0.0 million
- Procurement: $1,319.6 million
- Total funding: $1,319.6 million
- Procurement quantity: 1,767

Program Performance (fiscal year 2012 dollars in millions)

	As of 07/2003	Latest 06/2011	Percent change
Research and development cost	$637.2	$722.2	13.4
Procurement cost	$963.6	$1,180.0	22.5
Total program cost	$1,600.7	$1,902.3	18.8
Program unit cost	$.894	$.991	10.9
Total quantities	1,790	1,919	7.2
Acquisition cycle time (months)	85	104	22.4

The AARGM program entered production in September 2008 with its critical technologies mature and design stable, but without demonstrating its production processes were in control. The Navy halted operational testing in September 2010 after a series of missile failures caused by software issues and poor parts quality. The program reentered operational testing in August 2011 after Navy testers concluded that the anomalies identified during the program's first attempt at operational testing had been adequately addressed. Acceptance flight tests have screened out missiles of poor quality and validated recent improvements in the missile's reliability rate. However, concerns about the reliability and quality of the missiles being delivered are still being resolved.

Attainment of Product Knowledge

As of January 2012

Resources and requirements match	
• Demonstrate all critical technologies in a relevant environment	●
• Demonstrate all critical technologies in a realistic environment	●
• Complete preliminary design review	●
Product design is stable	
• Release at least 90 percent of design drawings	●
• Test a system-level integrated prototype	●
Manufacturing processes are mature	
• Demonstrate critical processes are in control	○
• Demonstrate critical processes on a pilot production line	●
• Test a production-representative prototype	●

● Knowledge attained
○ Knowledge not attained

Not applicable

2181 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

AGM-88E AARGM Program

Technology and Design Maturity

The AARGM program's critical technologies are mature and its design is stable. According to the program office, AARGM's two critical technologies—the millimeter-wave software and radome—were mature when the program entered production in September 2008. However, according to reports from DOD's independent test organization—the Director, Operational Test and Evaluation (DOT&E)—in 2009 and 2010, millimeter-wave sensors continue to pose a risk to the missile's reliability. The number of expected design drawings has also continued to increase since the start of production, but the missile's design remains stable.

Production Maturity

The AARGM program's production processes were not mature when it entered production in September 2008 and the program has experienced quality problems that have resulted in test failures and reliability issues. According to the program office, the contractor has identified 18 critical manufacturing processes, 8 of which are currently in statistical control. The program plans to demonstrate that all 18 processes are in control during its second initial production run, which is scheduled for completion by the end of the fourth quarter of fiscal year 2012. Since entering production, the program has experienced multiple production delays and operational test failures. According to Defense Contract Management Agency (DCMA) and DOT&E officials, the test failures were caused by both hardware and software issues. The hardware failures involved multiple subcontractors and were primarily attributed to poor parts quality. According to a DCMA official, supplier assessments conducted in the aftermath of the program's test failures found several problems with the prime contractor's management of its suppliers. For example, not all program requirements had flowed down to the subcontractor level, nor had subcontractors received updated drawings as design changes were made.

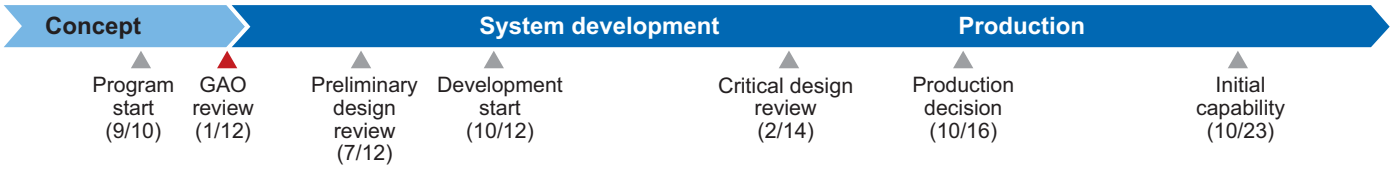
According to DCMA officials, the program office and prime contractor have taken actions to address the quality issues; however, in July 2011, Navy test officials evaluating the program's readiness to reenter operational testing reported that the reliability of the missiles coming out of the factory had not improved. The Navy has implemented additional controls to identify missiles of poor quality, in particular, requiring each missile to be flight tested for 3 hours before accepting them. This testing detected early unreliable missiles and supports the effectiveness of subsequent quality improvements. However, additional flight testing will be necessary to fully verify these actions.

Other Program Issues

The AARGM program has experienced multiple test delays, which have delayed the planned delivery of initial operational capability until April 2012. The program began operational testing in June 2010 after a 9-month delay due in part to concerns from DOT&E about the production-representativeness of test missiles. The Navy decertified the program from operational testing in September 2010 after hardware and software issues caused a series of missile failures. The program conducted additional testing between November 2010 and June 2011 and received approval to reenter operational testing in August 2011 after program and testing officials concluded that the anomalies identified during the program's first attempt at operational testing had been adequately addressed.

Program Office Comments

In commenting on a draft of this assessment, the Navy noted that the AARGM program continues to pursue should cost initiatives, awarding low-rate production contracts within should cost targets for planned quantities. AARGM reentered integrated testing in coordination with DOT&E and Navy testers in January 2011 with rescreened production assets and new software. All previous anomalies were addressed. An operational test readiness review was conducted in July 2011 and operational flights began in August. Since January 2011, AARGM has flown more than 300 hours on five F-18 variants, was successfully shot seven times, and will obtain initial operational capability in the third quarter of fiscal year 2012. The Navy stated that reliability continues to improve and is now over twice the threshold requirement. The program has improved production processes, developing the necessary repeatability and quality to request a full-rate production decision in June 2012. The Navy also provided technical comments, which were incorporated as appropriate.



2182 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Air and Missile Defense Radar (AMDR)

The Navy's Air and Missile Defense Radar (AMDR) will be a next-generation radar system designed to provide ballistic missile defense, air defense, and surface warfare capabilities. AMDR will consist of an S-band radar for ballistic missile defense and air defense, X-band radar for horizon search, and a radar suite controller that controls and integrates the two radars. AMDR will initially support DDG 51 Flight III. The Navy expects AMDR to provide the foundation for a scalable radar architecture that can be used to defeat advanced threats.

Program unit cost	NA	$659.887	NA
Total quantities	NA	24	NA
Acquisition cycle time (months)	NA	149	NA

AMDR plans to enter system development in October 2012 with some of the recommended knowledge about its technology and requirements. According to the Navy, AMDR's six critical technologies are expected to be demonstrated in a relevant environment before the start of system development. The program also plans to conduct a preliminary design review to refine its requirements. In September 2010, the Navy selected three contractors to build and test prototypes to demonstrate AMDR's critical technologies. Program officials stated that digital beamforming technology, which is necessary for simultaneous air and ballistic missile defense, will likely take the longest to mature. The Navy and shipbuilders have determined that a 14-foot active radar is the largest that can be accommodated by the existing DDG 51. AMDR is also being developed to be scaled up in size.

2183 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

AMDR Program

Technology Maturity

According to the Navy, all six critical technologies for the AMDR program are expected to be nearing maturity and demonstrated in a relevant environment before a decision is made to enter system development. They are currently immature. Program officials stated that digital beamforming technology—necessary for AMDR's simultaneous air and ballistic missile defense mission—has been identified as the most significant challenge and will likely take the longest time to mature. Digital beamforming enables the radar to generate and process multiple beams simultaneously, which results in more radar resources being available to support simultaneous air and missile defense. Program officials stated that this technology has been used before, but it has never been demonstrated in a radar as large as AMDR.

The AMDR's transmit-receive modules—the individual radiating elements key to transmitting and receiving electromagnetic signals—also pose a challenge. According to the program office, similar radar programs have experienced significant problems developing transmit-receive modules, resulting in cost and schedule growth. To achieve the increased performance levels required for AMDR, the contractor will likely use gallium nitride semiconductor technology instead of the legacy gallium arsenide technology. The new technology has the potential to provide higher power and efficiency with a smaller footprint. According to the Navy, this would reduce the power and cooling demands placed on the ship by the radar. However, gallium nitride has never been used in a radar as large as the AMDR, and long-term reliability and performance of this newer material is unknown. If these transmit-receive units cannot provide the required power, the program would either need to use the legacy technology and increase the power and cooling resources available for the AMDR, or accept reduced power and performance for the AMDR S-band radar.

Other Program Issues

The AMDR program entered technology development in September 2010 and the Navy awarded fixed-price incentive fee contracts to Northrop Grumman, Lockheed Martin, and Raytheon for S-band radar and radar-suite controller technology development. The contractors will build and test prototypes to demonstrate all critical technologies during a 2-year technology development period. The X-band portion of AMDR will be based on existing technology that is already mature. Additional software development will be required to integrate the two radars.

The Navy plans to install AMDR on Flight III DDG 51s starting in 2019. The Navy has yet to determine the size of AMDR for Flight III. According to draft AMDR documents, a 14-foot radar is needed to meet requirements, but an over-20-foot radar is needed to fully meet the Navy's desired integrated air and missile defense capabilities. However, the shipyards and the Navy have determined that a 14-foot active radar is the largest that can be accommodated within the confines of the existing DDG 51 deckhouse, even though AMDR is being built with the capability to be scaled up in size to meet future threats.

Program Office Comments

The program office concurred with this assessment and provided technical comments, which were incorporated where appropriate.

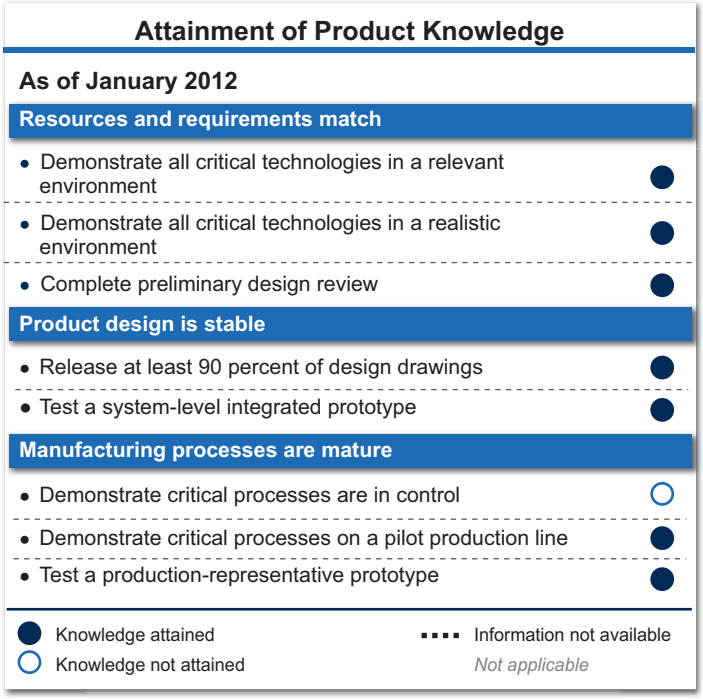
2184 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Apache Block IIIA (AB3A)

The Army's Apache Block IIIA (AB3A) program is upgrading AH-64D Longbow helicopters to improve performance, situational awareness, lethality, survivability, and interoperability, and to prevent friendly fire incidents. It consists of three sets of upgrades. For the first set of upgrades, AH-64Ds are sent to the factory for hardware changes. The second and third sets of upgrades are primarily software-related and can be installed in the field, reducing the time an aircraft is out of service and increasing training time for soldiers.

Source: U.S. Army.

Program Essentials



Prime contractor: Boeing
Program office: Huntsville, AL
Funding needed to complete:
R&D: $706.8 million
Procurement: $8,363.7 million
Total funding: $9,070.6 million
Procurement quantity: 610

Program Performance (fiscal year 2012 dollars in millions)

	As of 08/2006	Latest 12/2010	Percent change
Research and development cost	$1,155.6	$1,640.3	41.9
Procurement cost	$6,086.9	$9,096.8	49.4
Total program cost	$7,242.5	$10,737.0	48.3
Program unit cost	$12.031	$16.803	39.7
Total quantities	602	639	6.1
Acquisition cycle time (months)	79	82	3.8

The latest cost and quantities do not include the 57 new-build helicopters that are being acquired under the AB3B major defense acquisition program.

The AB3A program began production in October 2010 with mature critical technologies, a stable design, and manufacturing processes that had been demonstrated, but were not in control. The program is required to demonstrate its processes are in control prior to entering full-rate production. The program has begun installing the first of three sets of upgrades on AH-64Ds, and according to the program office, upgraded aircraft are on schedule to begin operational testing in March 2012. The design reviews for the second and third set of upgrades are planned for 2013 and 2015, respectively. These upgrades will be installed in the 2015 to 2017 time frame. In 2010, AB3 was restructured into two programs—AB3A for remanufactured aircraft and AB3B for new-build aircraft. New-build aircraft will be identical to the remanufactured ones and begin delivery in 2014.

2185 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

AB3A Remanufacture Program

Technology and Design Maturity

The AB3A program's one critical technology is mature and the design for the first set of upgrades is stable. The program has begun installing the first set of upgrades on AH-64D aircraft and the first upgraded aircraft entered service in October 2011. The development effort for the second and third set of upgrades, which are primarily software-related, is on track to begin in early 2012. According to the program office, these upgrades focus on reducing pilot and maintainer workload; expanding interoperability, survivability, and manned-unmanned teaming capabilities with other aircraft; improving targeting and navigation; and establishing the architecture for the integration of future technologies. According to the program office, the software development effort was preliminarily estimated at approximately 370,000 lines of code and this estimate was used to support the program's updated cost estimate for its production decision. Design reviews for these sets of upgrades are scheduled for 2013 and 2015, respectively, with follow-on operational testing planned for fiscal years 2014 and 2015.

Production Maturity

The AB3A program began production in October 2010 with manufacturing processes that had been demonstrated on a pilot production line, but were not in control. Prior to the production decision, the program concluded that its manufacturing readiness was at the level recommended by DOD guidance for the start of low-rate production. However, the program's manufacturing readiness level did not indicate that its production processes were in statistical control. The program is currently in the process of reassessing its manufacturing readiness. Before its planned July 2012 full-rate production decision, the program must successfully complete initial operational test and evaluation and meet other DOD criteria, which include demonstrating its processes are stable, in control, and meet acceptable process capability levels. AB3A has completed the first of three operational test readiness reviews and plans to hold the second and third reviews shortly before initial operational test and evaluation is planned to begin in March 2012. According to program officials, the AB3A is also on track to meet DOD criteria related to its performance, reliability, supportability, and manufacturing capability.

Other Program Issues

In 2010, following a Nunn-McCurdy unit-cost breach of the critical threshold, AB3 was restructured into two major defense acquisition programs—AB3A for remanufactured aircraft and AB3B for new-build aircraft. The original AB3 program involved taking legacy aircraft and remanufacturing them with upgraded capabilities. However, decreases in the numbers of legacy aircraft available for remanufacture, combined with increasing wartime demands, resulted in the addition of 57 new-build aircraft. The programs were separated to provide visibility into the cost, schedule, and performance of each segment. Structurally and technologically, the remanufactures and new-builds will be identical and the programs will share a common contract. New-build aircraft will cost significantly more than the remanufactured aircraft because of the need to procure all new parts. According to program officials, the production line for AH-64Ds did not have to be restarted for the AB3B program because it has been kept active for wartime replacements. The program expects to deliver the first new-build aircraft in fiscal year 2014. Foreign military sales have the potential to reduce the unit cost of the AB3A and AB3B. In 2012, the program will begin delivering foreign military sale aircraft to Taiwan, and several other countries are prospective buyers as well.

Program Office Comments

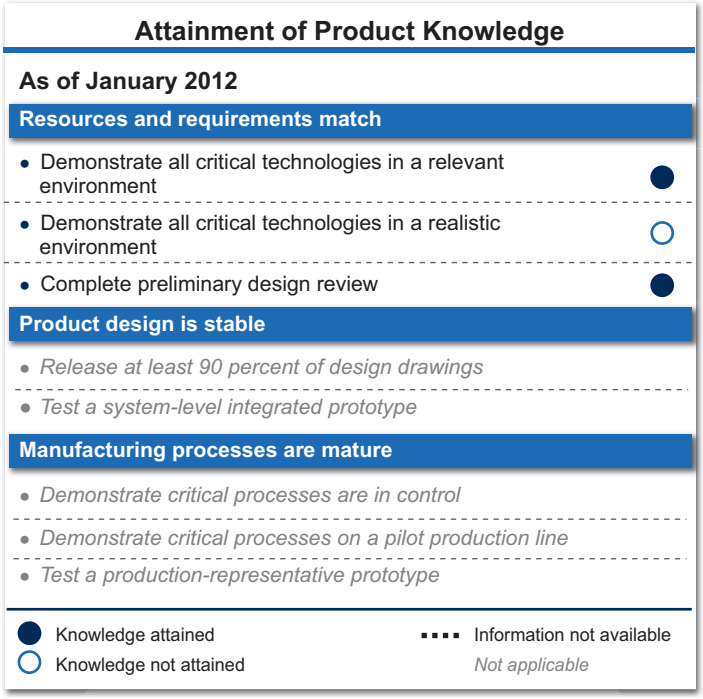
In commenting on a draft of this assessment, the Army provided technical comments, which were incorporated as appropriate.

2186 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Army Integrated Air and Missile Defense (Army IAMD)

The Army's Integrated Air and Missile Defense (IAMD) program is being developed to network sensors, weapons, and a common battle command system across an integrated fire control network to support the engagement of air and missile threats. The IAMD Battle Command System (IBCS) will provide a capability to control and manage IAMD sensors and weapons, such as the Joint Land Attack Cruise Missile Defense Elevated Netted Sensor System and Patriot, through an interface module that supplies battle-management data and enables networked operations.

Source: Northrop Grumman.



Program Essentials

Prime contractor: Northrop Grumman Space & Mission Systems Corp.
Program office: Huntsville, AL
Funding needed to complete:
R&D: $1,370.5 million
Procurement: $3,509.0 million
Total funding: $4,879.5 million
Procurement quantity: 285

Program Performance (fiscal year 2012 dollars in millions)

	As of 12/2009	Latest 08/2011	Percent change
Research and development cost	$1,595.2	$2,019.8	26.6
Procurement cost	$3,433.4	$3,509.0	2.2
Total program cost	$5,028.6	$5,528.8	9.9
Program unit cost	$16.988	$18.678	9.9
Total quantities	296	296	0.0
Acquisition cycle time (months)	80	81	1.3

IAMD's mission has not changed, but changes to its plans for integrating other systems have significantly increased the size of its software effort, delayed its design review by 8 months, and increased its development costs by over $400 million. These changes include adding Patriot launcher and radar functionality directly onto the integrated fire control network and increasing IBCS quantities. WIN-T integration is also a significant risk. The program is projecting that its design will be stable at its planned April 2012 design review, but it does not plan to demonstrate the design can perform as expected until August 2013. Additional cost increases may occur because the Army may increase the number of IBCS units it plans to buy. According to officials, DOD is expected to direct a new independent cost estimate and an updated program baseline.

2187 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

IAMD Program

Technology Maturity

The IAMD program entered system development in December 2009 with its four critical technologies—integrated battle command, integrated defense design, integrated fire control network, and distributed track management—nearing maturity, according to an Army technology readiness assessment based on a notional design. The Army updated the technology readiness assessment in March 2011 based on the winning contractor's design and reached the same conclusion about the technologies' maturity. The Office of the Assistant Secretary of Defense for Research and Engineering concurred with the assessment, but noted that integration with the Warfighter Information Network–Tactical (WIN-T) is a significant risk. It also noted that the assessment was based on modeling and simulations of the WIN-T and assumptions about performance. As a result, it recommended realistic, full-scale testing with WIN-T prior to a production decision. Program officials estimate that IAMD technologies will not be fully mature until its planned production decision in 2015.

Design Maturity

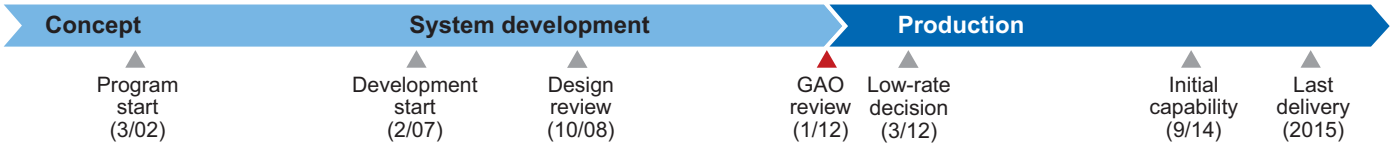
The IAMD program plans to release over 90 percent of its total expected drawings by its design review, but it does not plan to demonstrate that the design can perform as expected until August 2013—over a year later. As a result, the risk of design changes will remain. The IAMD design review has been delayed by 8 months to April 2012, in part because the program has made significant changes to the way it intends to integrate its planned engagement capabilities. These changes include adding Patriot launcher and radar functionality directly onto the IAMD integrated fire control network. The Medium Extended Air Defense System and Surface-Launched Advanced Medium-Range Air-to-Air Missile are no longer planned to be integrated with the system because those programs have been sharply curtailed or cancelled.

Other Program Issues

IAMD's development costs have risen by over $400 million or about 27 percent since development start and may increase further. According to program officials, the increases are primarily attributable to the decision to incorporate Patriot launcher and sensor functionality into the integrated fire control network and add a command and control module. According to program officials, increasing the number of IBCS units will provide for a common command and control at all echelons. Program officials now estimate the size of the software development at over 6.6 million lines of code—a 37 percent increase over the estimate at development start. In addition, about 63 percent will be newly developed code or auto-generated code. The cost of the added software has not yet been finalized, but program officials estimate that it will add 6 months to the software development effort. Other anticipated changes to the IAMD system, including an increase to the number of IBCS units, could increase costs further. According to program officials, DOD is expected to direct a new independent cost estimate for the program and an updated program baseline.

Program Office Comments

In commenting on a draft of this assessment, the program office noted that increases to the program include funds provided to add the Patriot sensor and launcher directly onto the integrated fire control network and IBCS units to provide full IAMD functionality at all echelons. The program is on schedule to conduct the design review in April 2012. Program delay is partially due to a reduction of $45 million shortly following the system development decision and the fiscal year 2011 continuing resolution. The Army IAMD program at development start was based on a generic design due to the competitive prototyping efforts of the contractors, and the originally estimated software lines of code were not specific to either contractor's approach. Since contract award, the contractor refined the estimates and software size should be stable going forward. To state that the software lines of code have grown 37 percent since development start is not wholly accurate since much of the increase is attributable to auto-generated code which requires less effort to complete. The program also provided technical comments, which were incorporated as appropriate.



2188 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

B-2 Extremely High Frequency SATCOM Capability, Increment 1

The Air Force's B-2 EHF SATCOM Increment 1 program will upgrade the aircraft's flight-management computer processors, increase data-storage capacity, and establish a high-speed network that will serve as the foundation for future B-2 upgrades, such as those being developed by the B-2 EHF SATCOM Increment 2 and the Defensive Management System Modernization programs. The development and successful integration of new disk-drive units and integrated-processing units is a primary objective for Increment 1.

Prime contractor: Northrop Grumman
Program office: Wright-Patterson AFB, OH
Funding needed to complete:
R&D: $62.6 million
Procurement: $127.4 million
Total funding: $190.1 million
Procurement quantity: 16

Program Performance (fiscal year 2012 dollars in millions)

	As of 05/2007	Latest 08/2011	Percent change
Research and development cost	$586.4	$497.7	-15.1
Procurement cost	$123.5	$127.4	3.1
Total program cost	$710.0	$625.2	-11.9
Program unit cost	$33.808	$31.258	-7.5
Total quantities	21	20	-4.8
Acquisition cycle time (months)	85	91	7.1

The B-2 EHF SATCOM Increment 1 program is expected to enter production in March 2012 with mature critical technologies and a stable design, but without fully demonstrating its production processes. A September 2011 operational assessment report indicated that Increment 1 is on track to meet system requirements; however, some software-related deficiencies must be resolved prior to initial operational test and evaluation in 2012. The program completed a production readiness review in May 2011, and expects to demonstrate sufficient manufacturing readiness prior to production. However, the program does not intend to demonstrate its critical manufacturing process is in control before starting production. According to the program office, it has demonstrated the capability to produce key components in a production-representative environment and established reliability through lab testing.

2189 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

B-2 EHF SATCOM Increment 1 Program

Technology and Design Maturity

All six B-2 EHF SATCOM Increment 1 critical technologies are mature and its design is stable. In February 2007, the program entered system development with all of its critical technologies nearing maturity. Since that time, these technologies have been matured and flight-qualified. The program office has reported that its design has been stable since its October 2008 critical design review. All expected drawings were releasable at that time and there has been no increase in the number of drawings since then. A September 2011 operational assessment report by the Air Force Test and Evaluation Center found that Increment 1 is on track to meet its effectiveness, suitability, and mission capability requirements; however, there are some software-driven shortfalls that need to be addressed prior to initial operational test and evaluation in 2012. In particular, the assessment report cited software deficiencies related to the system's communications capabilities and aircrew workload as critical issues requiring attention.

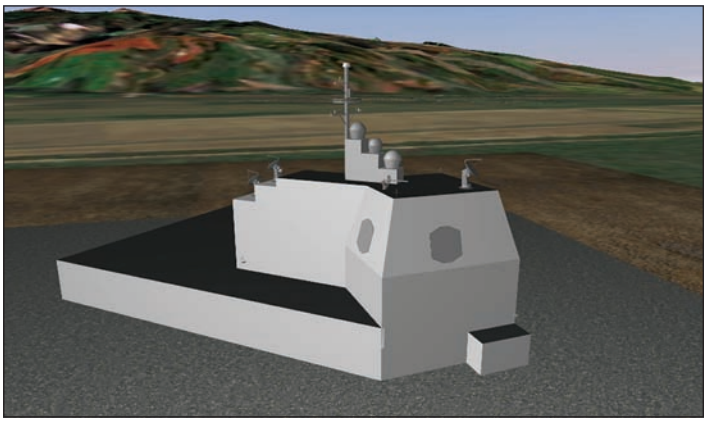
Production Maturity

The B-2 EHF SATCOM Increment 1 program is expected to enter production in March 2012 without fully demonstrating its production processes. The program completed a production readiness review in May 2011 and has identified one critical manufacturing process. According to the program office, by the start of production, manufacturing readiness will be at a level consistent with what is recommended in DOD manufacturing readiness level guidance. However, the program does not expect to demonstrate that its critical manufacturing process is in control—meaning that it meets our standards for production defect rates—before its production decision. In addition, the program will not be demonstrating manufacturing processes on a pilot line, but has employed alternative measures to demonstrate production maturity. For example, the program has demonstrated the capability to produce targeted components—disk-drive units, integrated-processing units, and a fiber harness—in a production-representative environment. According to program officials, they have also established that the integrated-processing and disk-drive units have high levels of reliability using data from lab testing.

Other Program Issues

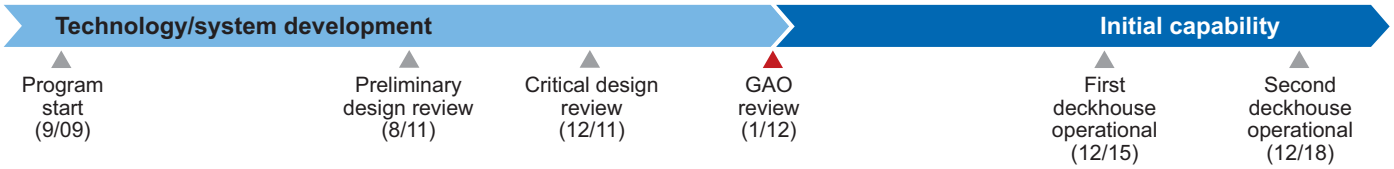
The B-2 EHF SATCOM Increment 1 has been largely able to overcome early delays in its test program. The program completed software certification in April 2010, flight testing began in September 2010, and the completion of initial operational test and evaluation is expected by late fiscal year 2012. The health of the test aircraft has continued to be a challenge for meeting the test schedule. Nevertheless, the program's planned software release to flight test in late fiscal year 2011 was completed and an operational assessment found the system to be on track to achieve its planned mission capability.

According to the program office, the B-2 EHF Increment 1 production decision was postponed from October 2011 to March 2012 to allow the negotiated contract price and the program's production cost estimate to be reconciled. The program has received Air Force approval to speed up production by pursuing a firm fixed-price two-lot buy instead of the previously planned three-lot buy, which should reduce production costs and provide for an earlier full operational capability.



Program Office Comments

In commenting on a draft of this assessment, the B-2 EHF Increment 1 program office stated that in addition to the program reaching a sufficient manufacturing readiness level prior to the start of low-rate initial production, the program plans to conduct an additional manufacturing readiness assessment during the initial phase of production in summer 2012 to demonstrate achievement of further maturity prior to the full-rate production decision planned for December 2012.



2190 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

BMDS: Aegis Ashore

MDA's Aegis Ashore is a planned land-based variant of the ship-based Aegis Ballistic Missile Defense system. It will track and intercept ballistic missiles using a vertical launching system, variants of the Standard Missile-3 (SM-3), and enclosures called deckhouses that contain a SPY-1 radar and command and control system. We assessed Aegis Ashore with SM-3 Block IB. DOD plans to first deploy this configuration in a host nation in the 2015 time frame as part of the European Phased Adaptive Approach Phase II.

Procurement quantity: TBD

Program Performance (fiscal year 2012 dollars in millions)

	As of 04/2010	Latest 03/2011	Percent change
Research and development cost	$835.1	$1,418.6	69.9
Procurement cost	NA	NA	NA
Total program cost	$835.1	$1,418.6	69.9
Program unit cost	$417.565	$472.864	13.2
Total quantities	2	3	50.0
Acquisition cycle time (months)	NA	NA	NA

Estimates in table above do not include missile costs.

Aegis Ashore is following a concurrent acquisition approach by entering system development prior to holding a preliminary design review and purchasing operational components prior to completing testing—both of which increase the risk of cost growth and schedule delays. The program office has now assessed its five critical technologies as mature or nearing maturity. However, several of these technologies may be less mature than reported. The system's design was stable by February 2012, but the risk of design changes will remain until it demonstrates the design can perform as expected by flight testing, which will not occur until 2014. Program management stated that the development is low risk because the technologies are already used by Aegis BMD ships and the program's ground and flight test schedule will confirm the capability by the time it is deployed.

2191 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

BMDS: Aegis Ashore Program

Technology Maturity

According to the Aegis Ashore program office, all five of its critical technologies are mature or nearing maturity. The program has assessed the SPY-1 radar, command and control system, SM-3 Block IB interceptor, and vertical launching system as mature and the multimission signal processor as nearing maturity. However, the maturity of some of these technologies may be overstated. The SPY-1 radar requires modifications for its use on land and other changes may be necessary due to host nation radar frequency issues. Program management officials stated at least some of these changes are software modifications, but the frequency issues may require other changes. The launch system must also be modified for use both on land and at a greater distance from the deckhouse. In addition, the maturity of SM-3 Block IB may be overstated because some of its component technologies have not been flight tested or have experienced failures in testing. The multimission signal processor also faces development challenges, and the Defense Contract Management Agency has identified its schedule as high risk. We have previously reported that a significant percentage of its software still needs to be integrated.

Design Maturity

The deckhouse design was 100 percent complete in February 2012, prior to the planned award of the deckhouse fabrication contract in the third quarter of fiscal year 2012. However, the program does not plan to demonstrate the design can perform as expected by flight testing until 2014, although there will be ground testing to demonstrate Aegis Ashore component integration prior to the flight test. As a result, the risk of design changes will remain until developmental testing is complete.

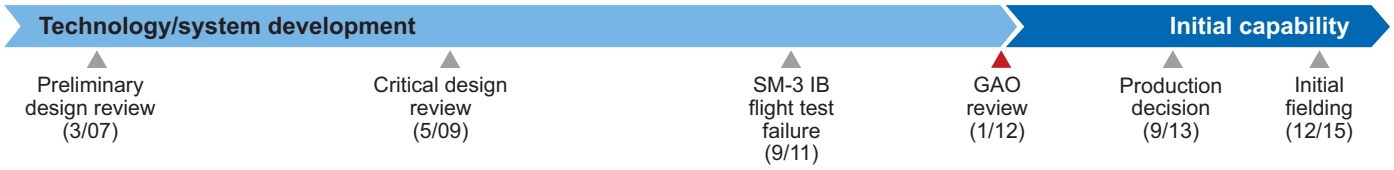
Other Program Issues

The Aegis Ashore program is following an acquisition approach that increases the risk of cost growth and schedule delays. The program began system development 14 months before completing its preliminary design review. We have previously reported that this review should be held prior to starting development to ensure that requirements are defined, feasible, and achievable within cost, schedule, and other system constraints. The program also contains concurrency between development and production, which increases the risk of late and costly design changes and retrofits. For example, the program is simultaneously acquiring the developmental test deckhouse and the operational deckhouse and is constructing the operational deckhouse first. In addition, the first developmental flight test of Aegis Ashore is scheduled for the second quarter of fiscal year 2014, at which point two deckhouses will have been constructed and other components will already be in production. Program management officials stated its concurrent schedule is low risk given its use of technology already used by Aegis BMD and modifications can be made to the deckhouse before it is installed in Romania. In addition, it stated that the current strategy has cost benefits and construction and testing efficiency advantages.

The program has experienced cost growth because of additional requirement costs. In 2011, the unit cost of Aegis Ashore grew, which the program attributed to costs for the reconstitutable deckhouse design that were not included in its baseline and the addition of hardware for a third site in Poland.

Program Office Comments

In commenting on a draft of this assessment, MDA provided technical comments, which were incorporated as appropriate.



2192 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

BMDS: Aegis Ballistic Missile Defense Standard Missile-3 Block IB

MDA's Aegis Ballistic Missile Defense is a sea- and land-based system being developed to defend against ballistic missiles of all ranges. It includes a radar, battle management and command and control systems, and Standard Missile-3 (SM-3) missiles. We reviewed the SM-3 Block IB (SM-3 IB), which will feature an improved target seeker, an advanced signal processor, and an improved divert/attitude control system for adjusting its course. It is planned to be fielded in the 2015 time frame as part of European Phased Adaptive Approach Phase II.

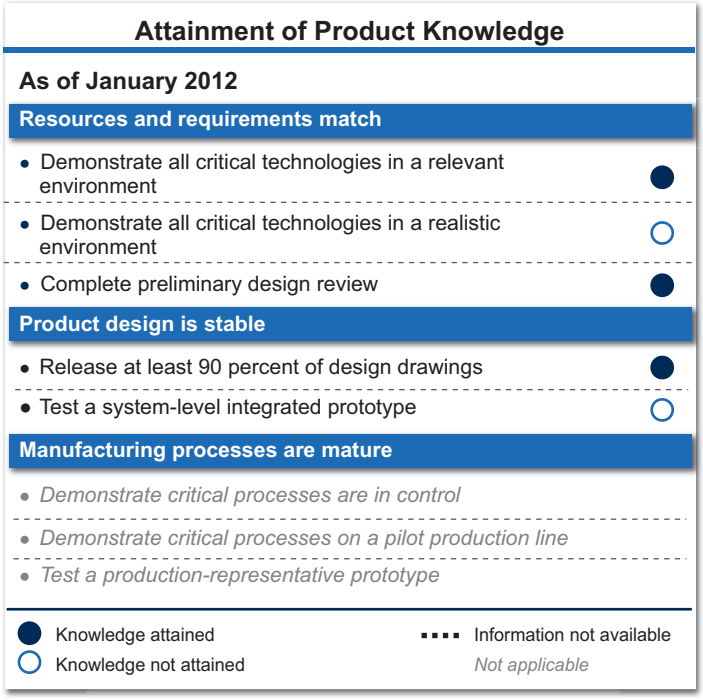
Program Essentials



Prime contractor: Raytheon
Program office: Dahlgren, VA
Funding FY12 to FY16:
R&D: $250.7 million
Procurement: $3,330.1 million
Total funding: $3,580.8 million
Procurement quantity: TBD

Program Performance (fiscal year 2012 dollars in millions)

	As of	Latest 05/2011	Percent change
Research and development cost	NA	$676.6	NA
Procurement cost	NA	$3,330.1	NA
Total program cost	NA	$4,006.7	NA
Program unit cost	NA	NA	NA
Total quantities	NA	370	NA
Acquisition cycle time (months)	NA	NA	NA

Costs are from program inception through fiscal year 2016.

The SM-3 IB will be at continued risk of cost growth, schedule delays, and performance shortfalls unless it demonstrates that the missile's critical technologies and design perform as expected before committing to further production. In 2011, the SM-3 IB failed during its first developmental flight test. At the time of the failure, MDA had contracted for 25 SM-3 IB interceptors, 18 of which were dedicated to flight testing. As a result of the flight test failure, MDA halted acceptance of SM-3 IB deliveries, convened a failure review board, and delayed key program decisions. In addition, two critical technologies—the throttleable divert attitude control system and third-stage rocket motor—still may not be mature. The attitude control system has not completed developmental testing or been successfully flight tested and the third-stage rocket motor may need to be redesigned.

2193 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

BMDS: SM-3 Block IB Program

Aegis BMD Element - Block 2004

According to the program, all five of its critical technologies—the third-stage rocket motor, throttleable divert attitude control system, reflective optics, two-color warhead seeker, and kinetic warhead advanced signal processor—are mature. However, the attitude control system has not completed qualification testing or been demonstrated in a realistic flight environment. In addition, the third-stage rocket motor, which was previously considered the most mature technology, may need to be redesigned to address issues discovered in flight testing. In its first developmental flight test in September 2011, the SM-3 IB experienced a failure involving one of its critical technologies and did not intercept the target. A failure review board is investigating the cause. The program plans to redo the failed test and conduct two additional intercept flight tests in 2012. Program officials expect that all SM-3 IB technologies will be flight-qualified and demonstrated through testing by the program's planned fiscal year 2013 production decision.

Design Maturity

The SM-3 IB's design has been relatively stable since its critical design review in May 2009, although design changes may be necessary to address issues discovered in testing. In addition, the program has not demonstrated that the missile's design can perform as intended through developmental testing. As a result, it remains at risk for further design changes, cost growth, and schedule delays.

Production Maturity

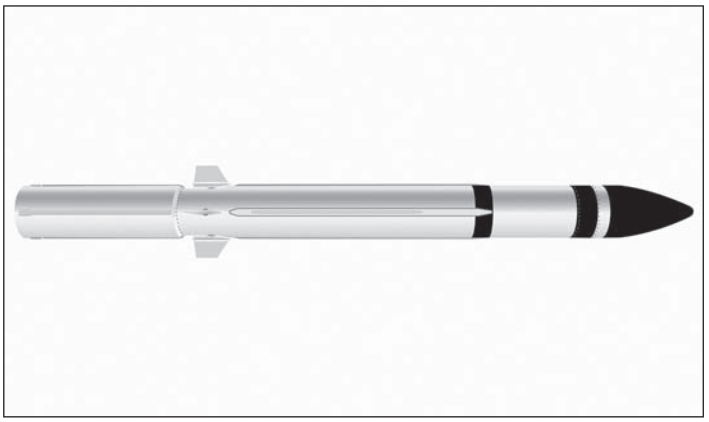
MDA has delayed the official start of operational missile production from February 2010 to the fourth quarter of fiscal year 2013. According to officials, MDA will not make this production decision until it completes initial developmental testing with production-representative missiles and shipboard systems.

The program has already contracted for 25 missiles, 18 of which will be used for developmental testing. The seven additional missiles could require costly rework and retrofits if the program decides to use them as operational assets as planned. According to MDA, additional missiles will also be used to prove manufacturing processes and for other purposes. MDA is also planning to purchase 46 additional missiles in fiscal year 2012. Any additional missiles ordered in fiscal year 2012 before the completion of flight tests needed to validate the missile's performance would be at higher risk of cost growth and schedule delays.

The flight-test failure investigation and possible redesigns are delaying both developmental and operational missile production. The program's acceptance of developmental missile deliveries and the production of certain missile components are on hold pending the results of the investigations. Program officials estimate that the failure investigations, design modifications, and additional testing will increase costs and they have not yet determined how many missiles may need to be refurbished.

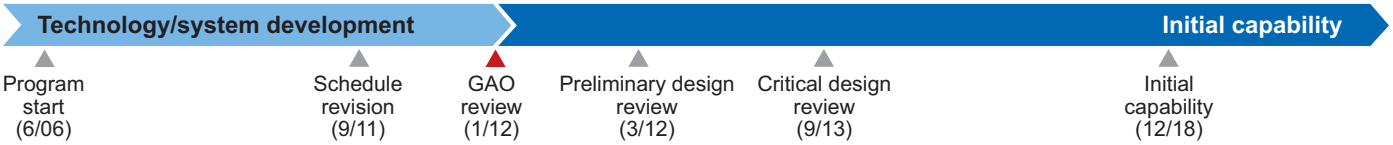
Other Program Issues

MDA originally planned to stop production of the SM-3 IA in 2010 and begin production of the SM-3 IB. However, SM-3 IB developmental issues have required MDA to twice delay the purchase of SM-3 IB missiles, purchase additional SM-3 IA missiles to avoid production gaps and keep SM-3 suppliers active, and reduce the planned initial purchase quantity of SM-3 IBs. The program's acceptance of SM-3 IA deliveries and the production of a missile component have been halted since April 2011, when an SM-3 IA missile experienced an anomaly during a flight test. The anomaly may have occurred in a component that is common to the SM-3 IA and SM-3 IB.



Program Office Comments

In commenting on a draft of this assessment, MDA provided technical comments, which were incorporated as appropriate.



2194 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

BMDS: Aegis Ballistic Missile Defense Standard Missile-3 Block IIA

MDA's Aegis Ballistic Missile Defense (BMD) is a sea- and land-based system being developed to defend against missiles of all ranges. It includes a radar, command and control systems, and Standard Missile-3 (SM-3) missiles. We reviewed the SM-3 Block IIA, a cooperative development with Japan, which will have increased velocity and range, a more sensitive seeker, and a more advanced warhead than other SM-3 variants. It is to be fielded with Aegis Weapons System 5.1 in the 2018 time frame as part of the European Phased Adaptive Approach.
